RADIOLOGY—Chairman Edward L Jenkinson Chicago Vice Chairman Ross Golden, New York, Secretary, John T Murphy, 421 Michigan Street Toledo, Ohio

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE

DEPARTMENT, JANUARY-JUNE 1935

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1925. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI" Bureau of Investigation, "E," Editorial, "C," Correspondence, "ME," Medical Economics, "ab," abstract, the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medical Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets follows the subject entry.

For author index see page 2454

WHAT SHOULD A PATIENT WITH ARTHRITIS EAT?

WALTER BAUER, MD
BOSTON

A time-honored question with physicians as well as with laymen is What should a patient with arthritis eat? If the type of diet prescribed for patients with arthritis is any criterion in answering this question, one is forced to conclude one of two things (1) that the diet indicated varies considerably from patient to patient or (2) that there exists no unanimity of opinion concerning the correct dietary for an arthritic patient.

CLASSIFICATION AND DIAGNOSIS OF JOINT DISEASES

Any discussion of the dietary in arthritis cannot be adequately presented without stressing the fact that an accurate diagnosis is the first requisite. In other words the physician's first duty, when confronted with a patient complaining of symptoms referable to the skeletal system is to determine whether or not the patient has arthritis, and if so, what type.

Therefore, some simple, workable classification of joint disease should be followed by all. The one that I employ is a slight modification of that proposed by Allison and Ghormley,¹ which is based on the pathologic changes and the etiologic agent.

CLASSIFICATION OF JOINT DISEASE

I Origin known

1 Traumatic

Synovitis
Loose bodies and cartilages
Sprains, etc.

2 Bacterial agent

Tubercle bacillus
Gonococcus
Staphylococcus
Streptococcus
Pneumococcus
Meningococcus
Typhoid bacillus
Dysentery organisms

Amebic
Bacillary

Spirochete of syphilis

Acquired

Congenital (tenosynovitis syphilitica)

Influenza bacillus

Brucella organisms

3 Neuro arthropathies (Charcot's joints)

Tabes dorsalis
Syringomyelia
Leprosy, etc.

4 Metabolic (?)

Gout

5 Constitutional

Hemophilia
Hysteria

6 Anaphylactic

Serum sickness

II Origin unknown or uncertain

1 Degenerative arthritis Synonyms Hypertrophic arthritis, osteo-arthritis type II arthritis

2 Proliferative arthritis Synonyms Rheumatoid arthritis, atrophic arthritis, type I arthritis, and chronic infectious arthritis

3 Rheumatic fever

With such a classification in mind, one should be able to differentiate and properly diagnose the various arthritides. However, it must be realized that there are other diseases in which the patient complains of symptoms referable to the skeletal system. There are many such diseases, the more common ones being undulant fever, chronic meningococcus septicemia, osteoarthropathy, low-grade osteomyelitis with multiple foci, hyperparathyroidism, myxedema, acromegaly, functional disease, and the like.

Thus, it must be apparent that no specific therapy can be prescribed for the patient with skeletal symptoms until he has been thoroughly studied and the proper diagnosis made.

DIETARY IN ARTHRITIS OF KNOWN ORIGIN

If a patient does have arthritis, what considerations should be given to his dietary? In the case of a patient with arthritis of known origin, is there any specific diet indicated? In the group of arthritides of known origin, the diet indicated is that which would ordinarily be prescribed whenever dealing with the particular disease or etiologic agent responsible for the arthritis. The one exception in this group is the patient with gout when the diet indicated is one of low purine content. It is noteworthy that, with the exception of gout, there is no specific diet for arthritis of known etiology.

DIETARY IN ARTHRITIS OF UNKNOWN OR UNCERTAIN ORIGIN

The arthritides of unknown origin represent the types of arthritis that have given rise to so much controversy concerning the diet in arthritis. Undoubtedly the chief reason for such controversy lies in the fact that these types of arthritis represent the group of unknown etiology and therefore have been subjected to certain

dietary regimens and speculations Without doubt such dietary regimens and speculations have been employed in order to evaluate their therapeutic effect as well as to determine whether or not diet is an important etiologic factor in arthritis of unknown origin

The dietary treatment of these two types of arthritis will be considered separately, because I look on them as being distinctly different disease processes, in no way causally related

DEGENERATIVE OR HYPERTROPHIC ARTHRITIS

Degenerative or hypertrophic arthritis is the type of arthritis known as senile arthritis, or the "chronic rheumatism" of the elderly The association of age and chronic traumatism in the production of this type of joint disease has long been known² The name degenerative arthritis^{2c} adequately describes the cartilage changes that are always observed in this type of joint disease Probably all other changes in the joints are secondary to these primary cartilage changes The first alteration noted is pronounced striation of the articular cartilage matrix, then fibrillation of the cartilage and the appearance of "crevasses" At this stage, microscopic examination reveals that the articular cartilage surface has a frayed appearance The ends of these fibrils may become detached, are finally worn down or disappear entirely Pronounced osteoid tissue formation may be seen, which later becomes calcified to form the marginal osteophytes The changes in the synovial membrane are not characteristic They are usually absent or at best minimal and never show any evidence of inflammation The change in the bone is chiefly a thickening of the subchondral plate Heberden's nodes exhibit all these changes At the onset Heberden's nodes may appear as red, swollen, at times fluctuant, tender terminal phalangeal joints, which ultimately appear as hard, ugly, disfiguring nodes which usually interfere very little with joint function

My associates and I³ are of the opinion that degenerative arthritis is the result of the "wear and tear" of increasing age and repeated trauma and not the result of an inflammatory process, metabolic disturbances or endocrine dysfunction, as some workers have contended⁴ We further believe that it is in no way related to proliferative (rheumatoid) arthritis We are of this belief for the following reasons

1 If the patellas of animals are permanently displaced by an operative procedure without entering the joint, intra-articular changes of a type similar to the changes observed in degenerative or hypertrophic arthritis are encountered⁵

2 If one examines human joints subjected to unusual use or repeated trauma, extensive changes indistinguishable from degenerative arthritis are found, whereas the

control joint (the opposite joint) shows no changes or only minimal changes⁶

3 If roentgenographic, macroscopic and microscopic examinations of human knee joints representing various ages from the first to the ninth decades are made, one notes that, with each succeeding decade of life beyond the second, the knee joint shows increasing pathologic changes, degenerative in nature and confined for the most part to the articular surface (These joints, at least six for each decade, were obtained at necropsy from individuals who, so far as we could determine, had never had symptoms of joint disease) In such a study one learns that the earliest as well as the most advanced lesions observed are identical in kind to those commonly spoken of as the characteristic lesions of degenerative or hypertrophic arthritis Arteriosclerosis is not an important etiologic agent in producing such lesions, because either minimal or marked changes may be found in patients with marked peripheral arteriosclerosis⁷

If hypertrophic arthritis is nothing more than degenerative joint changes due to the "wear and tear" of increasing age and repeated trauma, then what possible role can diet play in its treatment? If the symptoms complained of are confined to the weight-bearing joints and the patient is overweight, a reduction diet is indicated In prescribing such a diet, it is essential to maintain an adequate protein and vitamin intake Such a reduction diet should be at the expense of the carbohydrates and the fats to a point where the caloric intake is sufficiently lowered to bring about the required weight reduction Simple weight reduction will often result in the weight-bearing joints becoming symptom free because the load carried on the joint has been lessened Thus, one must appreciate that the beneficial results obtained with a reduction diet are due to simple weight reduction and not due to a reduced carbohydrate intake One must further realize that, at the time the marginal osteoid tissue proliferation is taking place, the periosteum may become elevated and, in consequence, pain may result Once this marginal osteoid tissue proliferation ceases and this tissue becomes calcified, pain may no longer be present In other words, some of the marginal joint changes may be responsible for the symptoms, and, once these have become quiescent, these symptoms will disappear Any treatment including dietary may therefore be given the credit for beneficial therapeutic results, whereas the improvement may well be due to the natural evolution of some of the joint changes This may well be the case in Heberden's nodes, which, as previously stated, are tender and painful in the earliest stages, whereas they subsequently become quiescent

PROLIFERATIVE OR RHEUMATOID ARTHRITIS

Rheumatoid arthritis still remains a disease of unknown etiology The fact that most of the people with rheumatoid arthritis have very pronounced constitutional symptoms has led most workers to believe that the joint symptoms are only a part of a disease that is constitutional in nature There probably are many factors that are causally related and responsible for this disease syndrome Certain clinical and laboratory observations suggest that infection plays a rôle Whether infection is the most important etiologic agent cannot be stated with certainty If it were, one might argue that the constitutional symptoms of patients so afflicted are merely a constitutional expression resulting

from the same infection. The answer to such questions must await the results of further investigations into the etiology of rheumatoid arthritis.

The pathology of the joints in this type of arthritis has been studied quite extensively by Nichols and Richardson,⁵ Hare⁶ and others.¹ These changes consist of proliferation of the synovial membrane and connective tissues of the subchondral bone spaces, round cell infiltration, increased vascularity and bone atrophy. The most marked and constant feature of the joints is that of proliferation; all other changes are secondary to it. Proliferation of the synovial membrane and of the connective tissue of the subchondral bone spaces is usually present. Destruction of the articular cartilage results if the proliferating synovial membrane called pannus grows over and eventually invades it. Invasion of the articular cartilage from below similarly results because of connective tissue proliferation in the subchondral bone spaces. These changes have been interpreted by some workers as being due to infection. The important thing to remember is that the intra-articular changes in rheumatoid arthritis are in no way similar to those of degenerative arthritis and are not causally related. It is true that the joints of an individual 50 or 60 years of age show the changes characteristic of degenerative arthritis as a result of the "wear and tear" of increasing age. Rheumatoid arthritis may at some later date develop in such an individual. If it does and if a joint so affected is examined, one will find the characteristic pathologic changes of both rheumatoid and degenerative arthritis. Furthermore, rheumatoid arthritis with the characteristic periarticular swelling of the metapalangeal joints (spindle fingers) may later develop in a person with Heberden's nodes and thus the telltale evidence of both diseases may be present. Rheumatoid arthritis may result in sufficient joint change so that the joint is no longer a stable joint. As a result of this mechanical instability, the joint may be subjected to increased trauma as well as "wear and tear," and in consequence one will find degenerative changes as well as the intra-articular changes of rheumatoid arthritis. However, such instances and observations are no reason or proof of the unitarian theory held by some workers.⁶ The examples just cited represent nothing more than the existence of two diseases in one individual.

One of the most important things to be remembered concerning rheumatoid arthritis is that the disease is characterized by remissions and relapses. Therefore, one will always find it difficult to evaluate the form of therapy employed because one is always confronted with the question: Is the improvement due to the treatment employed, or are we dealing with a natural remission occurring during the time a specific form of therapy was used? During a remission, a patient may become absolutely symptom free, but as a rule there are certain residual aches and pains. Many factors seem to play a role in precipitating a relapse or bringing about a remission. Remissions may last months or years. Because a disease characterized by remissions is being dealt with, one should be most cautious in speaking of cures. Certainly one should allow for a lapse of at least five years, preferably ten, before a patient is pronounced cured.

As previously stated, the question of the correct dietary to be employed in treating patients with rheumatoid arthritis has long been a subject of much controversy. In consequence, the medical literature contains many papers concerning "the dietary treatment of rheumatoid arthritis." Many of these reports reveal that the essential controls were omitted, and therefore a volume of otherwise valuable work is rendered invalid.

The following is a list of the diets that are being prescribed for patients with rheumatoid arthritis: (1) omission of the so-called acid fruits and vegetables, (2) allowing only one type of food substance at each meal (protein, fat or carbohydrate), (3) altering the acid-base balance of the diet, (4) omitting from the diet foods to which the patient is hypersensitive, (5) a low protein diet, (6) a reduced caloric intake and (7) a low carbohydrate diet.

An attempt will be made to evaluate each of these dietary prescriptions, if possible on the basis of (1) the rationale for prescribing them, (2) the results obtained, and (3) the deleterious effects that might ensue if the prescriptions were adhered to indefinitely.

Acid Fruits and Vegetables—The omission of the so-called acid fruits and vegetables would seem to be based more on fancy than on fact. The foods that are commonly called acid fruits include tomatoes, oranges, grapefruit, lemons and the like. These foodstuffs contain very weak organic acids, citric and malic acid, which are easily oxidized in the body. In great part they are present as salts of basic elements, and these are left in the blood as alkaline carbonates. Thus, it will be seen that acid fruits and vegetables serve as available alkali to the body. Furthermore, these foodstuffs represent the chief source of vitamin C. They also contain vitamin A. They are available the year round and are essential to a well balanced diet. Clinical experience with a high vitamin diet has not brought forth any contraindication to their use. They should be permitted and prescribed.

Faddists' Diets—Faddists have hit on the idea that one should not eat a mixed diet, contending that the presence of protein in the stomach interrupts starch digestion. This is a fallacy. There is no significance in this interruption. Starch digestion begins in the human mouth when mixed with saliva. Digestion is interrupted in the stomach when the fluid is acid, since starches are digested only in a slightly alkaline medium. Starch digestion is resumed in the small intestine, where the alkaline pancreatic juice furnishes the necessary amylolytic enzyme, the starch-digesting enzyme. Therefore the interruption is a physiologic one, occurring whether one eats an all starch meal or a mixed meal. Furthermore, certain animals—dogs, cats and cows—have no starch-digesting ferment in their saliva, but they thrive on foods rich in starches. All their starch digestion takes place after the food has left the stomach. It is unlikely that nature put these animals at a disadvantage in this respect.⁷

Acid-Base Balance of Diet—Some physicians occasionally prescribe a basic diet in rheumatoid arthritis because of the "tendency to an acid system." The "acid system" is a myth. As L. J. Henderson points out, "Neutrality is a definite, fundamental, and important characteristic of the organism." One need make no conscious effort to maintain a basic diet in an arthritic person any more than in the normal one. A well bal-

anced, well mixed, adequate diet in no way disturbs the acid-base balance of the body

Detection of Food Hypersensitivity—There are doubtless certain human beings who are hypersensitive to certain foods. In such instances there is usually a family history of allergic disease or the patient himself may be subject to asthma, hay fever, eczema or urticaria. If one suspects that a patient with rheumatoid arthritis is hypersensitive to certain foods and that this hypersensitivity to food is causally related to his arthritis, one can verify or disprove this assumption by carrying out certain simple tests. The responsible food may be found if the patient will keep an accurate diary of symptoms and of what he has eaten. Skin tests may give a hint as to the offending food, but ordinarily they are of little use. In a suspected case, the simplest experiment to carry out would be to have the patient live on only a few foods such as meat, rice, butter and sugar, and, if improvement is noted, other foods may be added one at a time. In this way, any foods which repeatedly result in an exacerbation of symptoms may be suspected of being causally related. I have never seen a patient with rheumatoid arthritis due to food hypersensitivity. Any such experiment would have to be very carefully controlled before being interpreted as conclusive.

A Low Protein Diet—The prescribing of a low protein diet is a relic from the days when rheumatoid arthritis was confused with gout. There is no justification for the limitation of proteins in the dietary of a patient with rheumatoid arthritis. There are many reasons why it should be liberal, such as the maintenance of a normal serum protein level, supplying iron, as well as the "antianemic" principle.

A Reduced Caloric Intake—Certain workers⁸ claim that the employment of a low caloric intake for a limited period of time is occasionally of distinct value. Under well controlled experimental conditions⁹ we have never been able to demonstrate any beneficial results from either a starvation or a semistarvation diet. Certainly it should never be tried in undernourished patients or persons with any complication such as fever or anemia. When a reduced caloric intake is employed, the experimental conditions must be extremely well controlled if one is to attach any significance to observed improvement.

Carbohydrate Restriction—Probably the one dietary restriction most frequently imposed on the patient with rheumatoid arthritis is a reduction of carbohydrates. The rationale of such a dietary is based on the following: (1) that a high percentage of rheumatoid arthritis patients have abnormalities of the colon and that such abnormalities are corrected by employing a low carbohydrate, high vitamin diet, particularly high in vitamin B,¹⁰ (2) that these patients have difficulty in utilizing starches,¹¹ (3) that patients with rheumatoid arthritis have a "delayed sugar" removal from the blood following the ingestion of 100 Gm of dextrose, (4) that a patient with rheumatoid arthritis improves on a low carbohydrate diet per se.⁶ Each of these points will be discussed separately.

We⁹ are in agreement with Archer⁶ and Haft¹² that there is no evidence to sustain the suggested theory that the observed colonic abnormalities are in any way specifically related to the disease rheumatoid arthritis. We further believe as they do that the incidence of such colonic abnormalities is no higher than one observes in a similar series of nonrheumatic cases. They probably represent "a manifestation of chronic disease states rather than a condition peculiar to chronic arthritis."

Carbohydrate indigestion and inability to utilize starches properly have been offered as evidence in favor of a low carbohydrate diet for rheumatoid arthritis.¹¹ Carbohydrate indigestion is probably a relatively rare disorder. Many of its supposed symptoms are very similar to those seen in functional disorders of the gastro-intestinal tract, which are quite common in the patient with rheumatoid arthritis. One will obtain a much clearer understanding of both carbohydrate indigestion and functional gastro-intestinal disturbances with the reading of Alvarez's writings, particularly his book on nervous indigestion. Any physician will profit by acquainting himself with this book. The finding of starch granules in the stool¹¹ is at best only suggested evidence of the inability to utilize starches, unless the starch-containing foods ingested by the arthritic and the normal subject are well controlled. If there is an inability to utilize starches, it must be due to a diminished secretion of the amylolytic enzyme. I am unaware that such a diminished secretion has ever been demonstrated in arthritic patients.

Demonstration of a "delayed sugar removal" from the blood has also been offered as evidence in favor of employing a low carbohydrate diet in patients with rheumatoid arthritis.⁶ This evidence is offered as strongly suggesting that, "whether or not any additional mechanism be concerned, denial to the muscular tissues of their usual degree of contact with the circulating blood interferes with the withdrawal of glucose so that when sugar is fed a 'lowered tolerance' results. This clearly suggests that circulatory changes contribute to the pathology of arthritis." A diminished sugar tolerance curve has not been demonstrated by some workers.¹² Archer⁶ states that, "in typical cases of rheumatoid arthritis, no evidence of a diminished sugar tolerance was demonstrated." In the routine work up of each patient with rheumatoid arthritis⁶ we do an arterial-venous sugar curve following the ingestion of 100 Gm of dextrose. We have noted that the high point in the curve often goes above what is considered normal, yet the majority of the curves are back to the fasting blood sugar level by the end of the third hour, always by the fourth. This higher type of curve would seem to be due to a delayed sugar removal, as shown by the fact that the arterial-venous separation at the peak of the curve is less than that observed in normal persons. The delayed sugar removal does not allow one to conclude that there exists any abnormality of carbohydrate utilization. In fact Cecil, Barr and Du Bois¹⁴ demonstrated a normal rate of utilization of ingested carbohydrates in the series of cases that they studied. The combination of a lowered metabolic rate and a delayed sugar removal is cited as reason for decreasing "the metabolic load," and this is best accomplished by a

reduction of carbohydrates. A significant lowered metabolic rate is seldom encountered in patients with rheumatoid arthritis.¹⁵ Du Bois¹⁵ sums up the situation by stating that the change in basal metabolism is such as might be expected in a crippling disease in which patients are forced to lead sedentary lives and remain bedridden. Various workers,¹⁶ making duplicate blood sugar curves on the same individual, have considered that any lowering of the second curve was the result of the treatment employed. However, Lennox,¹⁷ who has had a very unusual experience with repeated blood sugar curves on the same individual points out that he is loath to conclude that a lowered second curve is necessarily due to the treatment or the therapeutic procedures employed. Granted that a delayed removal may exist secondary to circulatory changes, what evidence has one that restriction of carbohydrates will favorably influence the disease with which the patient is afflicted? There are other diseases in which an associated delayed sugar removal can be demonstrated, such as hypertension¹⁸ and endocrine disturbances,¹⁹ yet we do not restrict the carbohydrate intake.

One can always argue that clinical experience proves that a low carbohydrate diet is efficacious in treating patients with rheumatoid arthritis.⁸ Certain workers²⁰ disagree with such a statement. As previously pointed out, much valuable therapeutic information concerning rheumatoid arthritis has become invalid because of failure to control adequately the experimental conditions. Therefore before any dietary treatment is instituted the patients must be in a "steady state." If, under such conditions, improvement is observed with great regularity, one may be led to suspect that the improvement is the result of the treatment.

What evidence has one that these patients may improve on a high carbohydrate intake? Lockie and Bowen²¹ have been kind enough to allow me to quote from their experience with high carbohydrate diets in patients with rheumatoid arthritis. They have had under observation four "extreme cases" on a mixed diet containing from 450 to 525 Gm of carbohydrate daily for from two to five months each and during this time have observed improvement. The only other treatment employed was light physical therapy and tonsillectomy in one patient. They state "Certainly the high carbohydrate diet has had no harmful effect. We believe some of the improvement which we have seen may be attributed to the general improvement in nutrition." Dawson writes "We have repeatedly put clinic patients on a restricted carbohydrate diet and then on an unlimited carbohydrate intake. As you can well imagine, the patients have always done better under optimal nutrition." He instructs his patients "to eat a well balanced diet consisting of everything and any-

thing well tolerated, especially fresh fruit and vegetables." He further states "There are few rheumatoid arthritis patients whom I would rather treat than those whose nutrition has been maintained in a faulty state on a low carbohydrate diet." My experience⁹ has been similar to that just quoted.

I therefore am of the opinion that one is not doing wrong to prescribe a well balanced, adequate diet for a patient with rheumatoid arthritis. Careful dietary histories obtained from our series of rheumatoid arthritis patients⁹ reveal deviations and abnormalities similar to those observed in the average American dietary, namely, a high carbohydrate intake in a large percentage, an inadequate protein intake in a fair percentage, and a low intake in calcium, phosphorus, iron and vitamins in a large percentage. In order to overcompensate for the inadequacies that exist in the average American dietary even though we have no proof that it is a deficiency disease, we advise observance of the following dietary to patients with rheumatoid arthritis. A

An Example of the Diet Frequently Given to a Patient with Rheumatoid Arthritis

Breakfast

Fresh fruit—average serving
Orange or grapefruit juice—1 glass
Eggs—2
Bacon—3 slices
Rye bread toast—1 slice
Butter—2 squares
Coffee with 40% cream

Dinner

Clear soup or broth
Meat or fish—average serving
Vegetable—average serving
Fruit or vegetable salad with mayonnaise
Extra vegetable—average serving
Milk or buttermilk—1 glass
Rye bread—1 slice
Butter—2 squares
Fruit dessert

Supper

Tomato juice—6 ounces
Liver chicken or lamb chop—average serving
Vegetable cooked—average serving
Fresh vegetable as lettuce tomatoes celery, etc.
Rye bread—1 slice
Milk or buttermilk—1 glass
Fruit dessert

- 1 Sugar bread and other desserts would be allowed in this dietary if the patient were not overweight.
- 2 In addition to the above we usually prescribe cod liver oil or one of the cod liver oil concentrates as well as some one of the vitamin B concentrate preparations.

high vitamin, high caloric (unless they are overweight) diet, adequate in respect to calcium, phosphorus and iron. In order to insure an adequate intake of vitamins A, D and B, we often prescribe cod liver oil or one of the vitamin A and D concentrates as well as a vitamin B concentrate. We advise restriction of carbohydrate intake for indicated weight reduction or when the maintenance of an adequate dietary is impossible because of the high carbohydrate intake. If such a diet contains too much roughage for the patient, it must be reduced but not at the expense of vitamins. In some arthritic patients with functional disturbances of the gastro-intestinal tract, it may be necessary to institute a soft diet which satisfies these requirements. This can best be done by following Alvarez's soft diet or some modification of it.

It is well for every physician to remember that there is no specific therapy for rheumatoid arthritis and that every one treating these patients should study them carefully, correct all abnormalities, treat the patient as a whole and observe the effect on the course of the disease.

Therefore, in treating patients with rheumatoid arthritis, one should always give them a list of specific instructions to follow. A copy of a high vitamin, high

caloric (if indicated) diet, adequate in respect to calcium, phosphorus and iron, in the form most suitable considering all factors, should be given to each patient. The list should also contain instructions pertaining to the taking of vitamin concentrates, rest, exercises, physical therapy or any procedure or therapeutic agent to be employed. All this enables the patient to carry out one's instructions to the last detail. Furthermore, such a regimen makes the patient realize that some one is genuinely interested in all the details pertaining to his life and his disease. This in turn often has a very beneficial effect on the patient's morale. Once it has improved, the patient is encouraged and makes an extreme effort to overcome his handicaps and fight his disease.

CONCLUSIONS

1 The first requisite in treating each patient with skeletal symptoms is to determine whether or not the symptoms are due to arthritis and, if so, to determine the type of arthritis. Not until this has been done should one attempt to prescribe a diet.

2 There is no specific diet for patients with arthritis of known origin other than the dietary which would ordinarily be prescribed whenever the particular disease or etiologic agent responsible for the arthritis is dealt with. Gout is the one exception.

3 Degenerative and rheumatoid arthritis represent the diseases one ordinarily thinks of as chronic arthritis. They are not causally related or due to the same etiologic agent.

4 (a) In degenerative arthritis, diet is indicated only in the presence of obesity, and then it should be sufficiently low in calories to allow weight reduction but adequate in every other respect.

(b) There is no evidence to prove that a low carbohydrate diet is indicated in rheumatoid arthritis, nor is there any proof that it is efficacious in curing the disease. Patients with rheumatoid arthritis should eat a diet high in calories (unless they are overweight), high in vitamins and adequate in respect to calcium, phosphorus and iron.

ABSTRACT OF DISCUSSION

DR. L. MAXWELL LOCKIE, Buffalo. Dr. Bauer has sounded a timely warning concerning the dietetic treatment of patients with rheumatoid or chronic atrophic arthritis. Many of these patients will lose weight quickly from their disease and it seems unnecessary to cut down the amount of carbohydrates or total number of calories unless the symptoms are aggravated. In a group of cases of atrophic arthritis studied by Dr. Bowen and myself at the Buffalo General Hospital, no untoward effects were noted during the months of observation while a high carbohydrate diet was being given, about 500 Gm of carbohydrates, 50 Gm of protein and 50 Gm of fat. These patients were better at the end of the study. None of them were made worse. Also during studies on a group of patients with typical gout it has been noticed that symptoms of the disease could be brought on by the use of a high fat diet. This was tried because of the observations of Harding on a group of normal women in various stages of pregnancy. He found that the blood uric acid would increase while they were given a high fat diet. Also Lennox noted that during periods of starvation the blood uric acid would mount and that when a high carbohydrate meal was given it could be brought down to normal within a day but that, if a high fat meal was given, no change was noted. So it seems that people with typical gout should be fed a diet high in carbohydrates and their symptoms should be carefully watched if they are given a diet low in carbohydrates and high in fat.

DR. WALTER BAUER, Boston. A few words of caution may be in order. To evaluate any form of special therapy in

patients with rheumatoid arthritis, one must have control study periods for each patient. The patient should first be treated with general measures such as rest, exercises for all joints and a well balanced diet until he comes to a steady state at which improvement is no longer observed. Once this steady state has been reached, one is justified in instituting the particular form of special therapy that one is interested in evaluating. If, under such conditions, results are obtained with any regularity, then and only then is one in a position to suspect that the treatment employed was responsible for the results observed. The fact must never be lost sight of that one is dealing with a chronic disease characterized by remissions and relapses and that therefore one must proceed with caution before speaking too enthusiastically concerning any special treatment. The same facts must be borne in mind when one speaks of cures.

THE TREATMENT OF PERFORATED "PEPTIC" ULCERS

HUGH H. TROUT, M.D.

ROANOKE, VA.

This paper deals only with the acute perforations that demand immediate operation. It does not concern those cases of perforation of marginal ulcers causing gastrocolic fistulas, chronic abscesses posterior to the stomach, intermittent leakage with blockage to which attention was called by Lund¹ in 1905, or even the forme fruste types of perforated ulcers recently described by Singer.²

The deductions reached are largely based on personal experience in the treatment of forty-one such cases. This experience has been greatly influenced, however, by numerous visits to other hospitals, conversation with other surgeons, and a careful review of the literature. Of course it is generally conceded, even by the most radical adherents of the nonsurgically inclined of medical men, that surgery offers the best hope of recovery. Therefore this discussion will be confined to surgical intervention in this condition, as considered under the following three headings:

1 Drainage after closure of the perforation

2 Advisability of immediate gastro-enterostomy following closure of perforation

3 Treatment of perforations on the posterior wall of the stomach and duodenum associated with hemorrhage

DRAINAGE AFTER CLOSURE OF THE PERFORATION

The type of closure is a somewhat different problem in each individual case. Therefore I shall not discuss this further than to state that I have been disappointed in finding in the vast majority of cases infiltration and other changes so extensive as to present some type of pyloroplasty.

I have been somewhat surprised in visiting various clinics to find some of the surgeons making it a rule to institute drainage after the closure of the opening, regardless of the time elapsing since the perforation, the results of smears of the peritoneal exudates, or the condition of the peritoneum.

Replies received from more than 100 surgeons gave the following information. These figures are only approximately accurate, owing to the fact that many of the replies were indefinite. However, these percentages are sufficiently correct to disclose that there was

Read before the Section on Surgery, General and Abdominal at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

no uniformity of procedure in the handling of these cases of perforation as regards drainage

About 20 per cent drain in every case. Most of these employ a drain through a remote stab incision. About 60 per cent drain only in the late cases or in cases in which there is evidently definite pus formation. About 20 per cent close the abdominal wall in every case without any drainage. In other words, 80 per cent do not use drainage as a rule.

Recently the dictum as regards peritonitis "when in doubt, drain" seems well on the way to being supplanted by the slogan "when in doubt, don't drain." No matter what one's individual views on this changing opinion might be, consideration should first be given to the nature of the fluid to be drained and the ability of the peritoneal cavity to assist in extrusion of the offending material. Therefore a study should be made of the bacterial flora, the gastric and duodenal contents, and the toxic effect of bile and pancreatic secretion in the peritoneum.

A review of the literature discloses that hydrochloric acid, even in minute quantities, has an inhibitory effect on the growth of bacteria. This work has been done many times in different parts of the world with such uniform results that to duplicate the experiments would be useless.

To any one interested in this subject the papers of the following authors are recommended: Poppens,³ Klinge,⁴ Krueger,⁵ Johnson and Arnold,⁶ Saunders, Holsinger and Cooper,⁷ Onufrio,⁸ Valdon,⁹ Saunders,¹⁰ Swift,¹¹ Arnold,¹² Risen, Sears and Downing,¹³ Nedzel and Arnold,¹⁴ and Furbush and Arnold.¹⁵

Since the bacteria one would expect to find in the stomach depend largely on the condition of the mouth, teeth and throat, a study of the bacterial flora of this locality should be made. It has been frequently demonstrated in the laboratory that minute quantities of hydrochloric acid will inhibit and prevent the growth of all such bacteria.

Numerous investigators have demonstrated by smears and cultures taken from the stomach that the higher the hydrochloric acid content the less the chances are of finding bacteria in the stomach. A clinical example of this is to be found in the fact that bacteria are frequently found in carcinoma of the stomach with its low acidity while they are practically never present in the ulcer case with its high acidity. Whether the action of the hydrochloric acid only inhibits the growth of bacteria or destroys them is of but little practical impor-

tance in deciding on the question whether or not to drain.

Johnson and Arnold⁶ demonstrated the bactericidal power of the acidity of the gastric juice in *in vivo* experiments, using dogs. They concluded that the "acid-secreting stomach does not seem actually to destroy bacteria."

Lloyd Arnold¹² proved that "there was a correlation between the acid-base balance of the contents of the lumen of the stomach and the viable bacteria. When free hydrogen ions appear, the bacteria within the contents are nonviable. Bacteria are viable when an acid-deficit condition exists." In other words the action of the acid gastric juice on bacteria has been shown to be more bacteriostatic than bactericidal in nature.

Numerous surgeons have taken smears and cultures of the stomach and duodenal contents while doing operations for peptic ulcer. These smears and cultures have uniformly been negative for bacteria in smears and colonies on culture. The following quotation¹⁰ is interesting in this connection:

Stomach. Smears made from the gastric contents during digestion show a large variety of organisms: gram-positive cocci, yeast and sarcinae, sporing bacteria, vibrios, spirochetes and leptothrix-like organisms. With the exception of the spore-bearing aerobes (*B. mesentericus*, *B. megatherium*, *B. subtilis*), which are probably carried in with food, the bacteria are largely derived from the mouth. Coliform organisms are rarely isolated and are usually of *B. lactis-aerogenes* type. *B. Welchii* and *B. sporogenes* may be found along with lactic acid bacilli (*Boas-Opper bacillus*) where there is delay in emptying the stomach. Three to four hours after a meal the gastric contents are practically sterile.

In contemplating whether or not to drain it might be well to consider the condition of the teeth, tonsils, and the like, and if the mouth was found to be foul, such a finding might justify drainage of the peritoneum.

Klinge⁴ considers the gastric mucosa to have a bacterial killing power independent of its hydrochloric acid secretion.

On the other hand, Knott¹⁷ has shown that the only lethal agent to bacteria in the stomach is the free hydrochloric acid, which, being in an almost completely ionized state, provides a high concentration of hydrogen ions. On this hydrogen ion the bactericidal power of mineral acid depends. He has demonstrated that the other secretions of the stomach are not inhibitory to infective bacteria. He found that the strengths of free hydrochloric acids required to inhibit the subsequent growth of various pathogenic bacteria after twenty minutes' exposure fell within the range of free hydrochloric acid values encountered in normal gastric juice.

I have taken smears of perforated "peptic" ulcers and cultures from the peritoneal cavity of twenty-one patients but have failed to obtain any definite information. This failure could easily be due to the fact that the culture contained some hydrochloric acid. And, in addition, my failure to grow cultures might easily have been due to not employing the technique of anaerobic culture recently worked out by Meleney and his co-workers.¹⁸

To any one especially interested in the problem of the immunologic and serologic side of peritonitis, the

articles of this group of experimenters will be found to be extremely instructive. They not only studied the subject of peritonitis from an experimental point of view but also carefully analyzed clinically 106 cases of secondary peritonitis. However, in this group there was not a single case of peritonitis due to perforated gastric ulcer. There were two due to perforations of the duodenum in this group. One of these showed no bacteria on culture or smear. The other case showed nothing on smear but yielded four different species on culture. It is interesting to note the prognostic value these workers attach to the comparison of the smears of the peritoneal fluid made at the time of operation with the cultures—if fewer species appeared in culture than were seen on smears the patients all recovered.

In addition to the inhibitory effect of small quantities of hydrochloric acid on the growth of bacteria, the bacteriostatic influence of the peritoneum has to be considered as a contributing factor in the patient's defense. On the other hand, there is much to be learned concerning the synergistic or antagonistic effects of multiple bacteria found in peritonitis of different types. This has also been fully dealt with by Meleney and his associates.¹⁹

In a recent article Roberts and Johnson²⁰ state that the aseptic peritoneal cavity is a misnomer. Their studies led them to believe that in 80 per cent of instances a growth can be obtained from cultures taken from within the peritoneal cavity, irrespective of whether the patient is male or female or of any clinical evidence of intraperitoneal inflammatory reaction. Further, they found that the flora from within the peritoneal cavity differed markedly from the air of the operating room and therefore arrived at the conclusion that bacteria were normally found in more than 80 per cent of cases.

There have been too many peritoneal cavities opened without harmful effects, however, for such an observation to be of much practical importance, and certainly very little possible bearing on the subject of drainage in perforated "peptic" ulcers.

The bacterial flora of the duodenum presents a somewhat different picture from that normally found in the stomach. It is well known that bacteria flourish in the duodenum in patients suffering with chronic biliary tract and gallbladder disease, provided there is a low acidity present. In these cases of perforated "peptic" ulcers, however, the acidity is practically always excessively high and in the vast majority of cases sufficiently high to prevent the growth of bacteria even in the duodenum in those cases of duodenal ulcer associated with biliary tract disease. In the majority of cases the perforation is so close to the pylorus and the edema so extensive that it is impossible to state accurately whether the ulcer is gastric or duodenal.

Of course, both bile and pancreatic juices are badly tolerated by the peritoneum, but the quantity of either of these is so small that they do not present a serious problem as regards immediate mortality in these cases.

Wangensteen²¹ and Walters and Bollman²² have described the results of larger collections of bile in the

peritoneal cavity. Any one interested in this subject will find both of these articles instructive.

While it might sound like a trivial and unnecessary suggestion, still I feel it to be highly important to protect the incision with several more layers of gauze or towels than are usually employed—a point apt to be omitted in the surgeon's natural desire to close the perforation as quickly as possible.

It is my practice to have an assistant aspirate the peritoneal cavity, especially the two lumbar fossae and the pelvis, by means of a suction tube, while the operator is closing the perforation, and then to close the abdomen without drainage. It is not unusual to aspirate 1,000 cc or more of fluid. In the exceptional and very late case, a lumbar or pelvic puncture drain might be an aid. I employ silver wire, after the manner of Shipley,²³ or some nonabsorbable through-and-through sutures in addition to the usual closure, so in case the incision is contaminated the skin suture can be removed and pack the incision wide open with some antiseptic gauze. Up to the present time the necessity to open a contaminated incision has arisen only in three cases—two of these patients recovered, and one died.

In my series of forty-one cases, secondary abscesses have developed in four, and the possibility of this postoperative complication should be constantly kept in mind, for very early incision and drainage of such abscesses is essential to the recovery of a patient who has previously withstood the demands made on his defensive mechanism. One of these four patients with secondary abscess died.

It is my misfortune to have seen in consultation four cases in which a drain had been placed somewhere near the point of closure of the perforation and the drain brought out through the incision. Either gastric or duodenal fistulas developed in all four of these patients, and all died after lingering for days discharging irritating fluid through a fistula onto a very painful, macerated skin. Perhaps this unhappy experience has done much to focus my attention on the necessity of not employing drainage in these cases except when absolutely necessary, and then to have the drain placed remote from the suture line.

ADVISABILITY OF IMMEDIATE GASTRO-ENTEROSTOMY FOLLOWING CLOSURE OF PERFORATION

For some years many surgeons advocated doing a gastro-enterostomy after the closure of the perforation in every case in which the patient's general condition would justify such a procedure. Unquestionably, these patients had a far more comfortable postoperative course with a gastro-enterostomy, but the nasal suction tube, as described by Wangensteen,²⁴ has done away largely with this indication for an immediate gastro-enterostomy.

A few years ago a gastro-enterostomy was generally considered by surgeons to be the proper procedure in the treatment of duodenal ulcer, but recently the internists have certainly demonstrated the great value of medical treatment.

I now feel that, when the patient's general condition is good, the perforation fairly recent and the site of ruptured ulcer such as to produce evident obstructive symptoms later, a gastro-enterostomy is indicated.

However, in the vast majority of cases the less that is done to these patients the better are their chances of recovery.

Only three of my patients have had a subsequent operation done for pyloric obstruction. In my series of forty-one cases a primary gastro-enterostomy has been done in eight cases. One of these eight patients died. This case might have been unwisely selected for further operative intervention rather than the closure of the perforation.

TREATMENT FOR PERFORATIONS ON THE POSTERIOR WALL OF THE STOMACH AND DUODENUM ASSOCIATED WITH HEMORRHAGE

In this series I have had three cases of acute perforation on the posterior wall, and all three of them were associated with repeated massive hemorrhages. All these patients died. If I have another similar case I shall certainly try the method of Allen and Benedict²⁵ and do a partial gastric resection, which they have so well described. Any surgeon who has seen one of these cases is not favorably impressed with the statement so frequently made that "bleeding ulcers don't perforate and perforating ulcers don't bleed." Alton Ochsner has operated successfully in one such case by the Allen and Benedict method. This was done two months ago and I am reporting this with his permission.

Carefully supervised postoperative medical treatment is most essential in all cases. In fact, surgery is only an aid, though a most important one, in the course of the medical treatment of all "peptic" ulcers.

Only twelve out of the forty-one patients had been treated for peptic ulcer previous to admission to the hospital. Nine of my forty-one patients have died, or a mortality of about 22 per cent. This includes two patients who died shortly after admission to the hospital without having had an operation.

The physicians who have referred these patients to me have sent them into the hospital at an earlier period than is usually done in other localities, and to them should be given the credit for this satisfactory showing. After all is said and done, the combination of early diagnosis and immediate operation contributes most to a low mortality rate.

CONCLUSIONS

- 1 Drainage of the peritoneal cavity should be avoided if possible.
- 2 Continuous gastric suction through a nasal tube has decreased the indications for an immediate gastro-enterostomy.
- 3 Partial gastric resection is the operation of choice in those cases of posterior perforations of the stomach or duodenum which are associated with massive hemorrhage.

Jefferson Hospital

ABSTRACT OF DISCUSSION

DR. ROY D. McCLEURE, Detroit. In 1900 Drs. Harvey Cushing and L. E. Livingood (*Johns Hopkins Hosp. Rep.* 9:543-591, 1901) published a comprehensive and thorough study of the bacteriology of the gastro-intestinal tract, showing the bacterial flora at different levels and the time at which they were found. The main conclusion, which I think has a bearing on this subject, was that the bacteria found in the upper gastro-intestinal tract depended on the length of time after the meal had been taken and the type of bacteria which had been in that meal. They also found—thirty-four or thirty-five years

ago—that the bacteria which did persist were the streptococci. I have gone over a series of cases in the Henry Ford Hospital and in seventy-five cases, in all of which drainage was done there was a mortality of 26 per cent, which is 2 per cent higher than Dr. Trout's, which in that small group of cases perhaps meant one or two more deaths. In studying the cause of this death rate it is hard to arrive at definite conclusions. Of the operators in our clinic one man who was a resident surgeon had four cases without a death, another man, an associate of mine, had eleven cases with four deaths. I know that it was not a matter of skill or of the treatment. There are several other factors concerned in the cause of death that perhaps should be considered. First, of course, is the length of time elapsed since the perforation. I do not believe that is as important a point as is the amount of soiling. The amount of soiling depends, of course, on the size of the perforation, and this determines the amount of adhesions that the omentum or intestine makes over that perforation. If it is a large sudden perforation there is very little chance of such adhesions and there is a great amount of soiling. The third point is the one first brought out by Dr. Cushing: the length of time after the meal and the type of bacteria present in that meal. Another definite factor in the high mortality is the amount of surgery done. Dr. Trout has just said that gastro-enterostomy or resection should be done at the time of operation. My conclusion is that the less done at the time of operation the better. I believe that with the help of the Rehfuß tube, simple closure of the ulcer and drainage (perhaps he is right about no drainage) the patient can be gotten over the immediate shock and at a later date, as is now being practiced in our clinic: resection or posterior gastro-enterostomy can be done.

DR. J. M. DONALD, Birmingham. I realize that it is undesirable to attempt to employ any one operation for every case. This is especially true in surgery of the stomach or duodenum. I should like, however, to discuss the treatment of acute perforation of a duodenal ulcer, on the anterior wall by a local excision followed by pyloroplasty. In the cases seen early, even under twelve hours the duodenum is easily accessible and in the absence of obstruction local excision, followed by a closure as in pyloroplasty, can be done practically as safely as a simple closure. I believe that simple closure should be reserved for those cases in which the condition of the patient does not warrant any more surgery than is absolutely necessary, when the perforation has been present for many hours, when the duodenum is fixed by adhesions and cannot be easily mobilized, and in the presence of obstruction. The advantages of a local excision with a pyloroplasty are, first, that the ulcer is removed, second, that the pylorus is made larger than it was before, relieving the possibility of future obstruction, and third that the patient has the same chance of a permanent cure that he would following the operation for nonperforated ulcer. Dr. Judd in a large series of cases in 1930 reported 90 per cent of cures with the excision of nonperforated duodenal ulcer, whereas Gilmour and Saint reported sixty-four cases in which they did a simple closure for acute perforation, and in 33⅓ per cent over a period of five years a second operation was necessary. Another advantage of this operation is that by excising this friable, infected, ulcerated tissue surrounding the perforation, and bringing the normal duodenal wall to the stomach and closing it in a transverse fashion one obtains a cleaner and a more satisfactory closure. This operation takes but a few minutes longer than the simple closure and in a small series in my experience the convalescence has been smoother and was followed by fewer complications than in those following simple closure. I think that prophylaxis ought to be considered as well. Not only do a large percentage of the cases give a history of a preexisting peptic ulcer, but the history is suggestive of a penetrating type of ulcer. The pain is more severe than in the ordinary peptic ulcer. When the x-rays show a penetrating ulcer, surgical intervention should be urged in order to excise the ulcers before they reach the point of perforation. I feel that, if this plan is followed, the mortality will be materially lowered.

DR. HUGH H. TROUT, Roanoke, Va. I failed to mention that a review of the literature, as well as my own experience, shows that in less than 10 per cent of the cases in which a gastro-enterostomy or any type of plastic operation had been

²⁵ Allen, A. W. and Benedict, E. B. *Acute Massive Hemorrhage from Duodenal Ulcer*. *Tr. Am. S. A.* 61:257, 1933.

omitted was a secondary operation for the relief of obstruction required. My attention to omission of drainage was called by a very unpleasant experience with four cases in which drainage had been done. I admit that the drainage had not been properly done. It had not been done in our clinic but it might just as well have been done there. Drainage had been done through the abdominal incision and the drain was placed close to the perforation. A fistula developed in all four and all four patients died with a fistula draining a painful, irritating fluid on a macerated skin. My experience in going over these forty-one cases has been that only six of the patients knew they had an ulcer. In talking to a large number of surgeons I found that practically all of them agree that only a small percentage of the patients knew they had an ulcer before the acute perforation.

CEREBRAL NEOPLASMS

THE DIAGNOSIS IN THE ABSENCE OF GENERALIZED INTRACRANIAL PRESSURE PHENOMENA

A. E. BENNETT, MD

AND

J. J. KEEGAN, MD

OMAHA

The classic cardinal symptoms of increased intracranial pressure are lacking in from 15 to 30 per cent of large groups of patients with intracranial tumors, according to the studies of many observers. Since a diagnosis of cerebral neoplasm is rarely made in the absence of pressure phenomena, it is our belief that many more patients die of unrecognized cerebral neoplastic disease than the reports in the literature would indicate.

Headache, the most prominent symptom of brain tumor, is absent in at least 10 per cent of cases,¹ while papilledema, considered by many observers the most valuable pressure sign, is absent in from 15 to 30 per cent of cases.² Vomiting, usually a late symptom dependent on high grade internal hydrocephalus, occurs still less frequently. Other pressure phenomena are more uncommon. Headache, vomiting and choked disks are present together in only about 60 per cent of cases.¹

The diagnosis of cerebral neoplasms has been so intimately linked with the symptom triad of intracranial pressure that one is often misled into believing tumor to be excluded if pressure signs are absent. Of recent years, however, more reports are appearing of cases diagnosed early before the appearance of late pressure symptoms. The incidence of these early diagnoses will increase, owing to refinements in diagnosis through mechanical aids, such as spinal manometric readings, combined ventricular and lumbar estimations, improved roentgenologic technic and the use of encephalography in obscure lesions.

Some neurologists feel that in clinics in which mechanical aids are resorted to frequently, neurologic diagnostic acuity is lacking. This criticism may be true in many instances, but very excellent careful diagnostic observers state that frequently they cannot make nor even suspect a diagnosis of tumor from the symptoms presented. With this group of patients showing no

pressure phenomena, one must use the technical aids of the laboratory to improve the percentage of correct diagnoses.

It has been our privilege in the last few years to study twelve tumor cases of this type, verified as space consuming lesions by encephalography, operation or necropsy. In all these instances generalized increased intracranial pressure phenomena interpreted by symptoms or signs, including increased manometric cisternal or spinal readings, were lacking. We feel that a study of these cases is worthy of report in order to stimulate interest in earlier diagnoses of cerebral neoplasms.

Many causative factors in the production of increased intracranial pressure are in dispute. There are several theories as to the cause of papilledema. It is fairly well agreed, however, that the principal cause of cranial hypertension is disturbance of the outflow of cerebrospinal fluid. This interference is usually some degree of block of cerebrospinal fluid in the ventricular system, producing internal hydrocephalus or obliteration of some of the subarachnoidal channels, interrupting the absorption of cerebrospinal fluid. The tumor seems to raise intracranial tension very little until its growth interferes with the circulation of the cerebrospinal fluid. The location of the tumor is highly important in the production of early or late pressure phenomena. Midbrain and subtentorial tumors practically always show early pressure signs, while frontal lesions may develop to unusual size without increased pressure.

Many cases are reported that markedly distort or compress the ventricular system, even producing obstruction of the cerebellar foramen magnum and yet do not show an increase of pressure sufficient to produce papilledema.⁴

Fundus change usually goes hand in hand with hypertension of the cerebrospinal fluid. We usually expect to find blurring of the nasal margin with a spinal manometric reading around 20 mm of mercury. This means that papilledema is often a late manifestation of increased pressure, and the more frequently spinal manometric readings are made the larger will be the number of cases detected in the early stages with beginning increased tension from 10 to 20 mm of mercury. The manometer in our hands gives the most reliable and earliest guidance in the diagnosis of a pressure lesion.

Many still are afraid to use lumbar puncture in suspected cases of brain tumor. Masson,⁵ in a review of spinal puncture studies in 200 patients with tumors, concluded from the evidence of his series that there is little danger in lumbar puncture even in patients with tumors of the posterior fossa. Our rule is to exercise great care with spinal or cisternal punctures in the presence of papilledema. We still consider that pressure lesions of the posterior fossa contraindicate puncture because of the ever present danger of inducing cerebellar herniation,⁶ unless the information is necessary to make a diagnosis. In any case of suspected tumor in which spinal puncture is done, a 22 gage needle should be used for the first puncture to reduce to the minimum possibilities of cerebellar herniation.

Local pressure signs may be highly diagnostic long before generalized pressure manifestations appear.

From the Divisions of Neurology and Neurosurgery, University of Nebraska College of Medicine.

Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the authors' reprints.

Such roentgenographic signs as evidence of local calcification, rarefaction of bone, increased diploic vessel marking and shifting of the pineal shadow are valuable aids in diagnosis and localization. These occasionally give leads to the diagnosis of tumor before neurologic signs are present. Brain² found that 23 per cent of his tumor cases presenting normal optic fundi showed areas of calcification suggestive of a tumor. For this reason all patients suspected of having tumors should have roentgen studies of the skull made even in cases in which encephalography is contemplated.

Epileptiform attacks, grand mal, petit mal or jacksonian seizures are often the first symptoms of cerebral neoplasm and occur frequently before generalized pressure phenomena appear, in some instances years ahead of other tumor symptoms. Parker⁷ found in 313 cases of brain tumor that sixty-seven patients, or 21.6 per cent, had major seizures. In thirty-eight of these cases the convulsions were the initial symptom, in thirteen cases, or 4.1 per cent, seizures preceded all other symptoms or signs by one or more years. Gotten⁸ reported three tumors found on routine encephalographic examination in fifty-six cases of so-called epilepsy. Two of these tumors were completely removed. The incidence of unsuspected focal lesions as a cause for epilepsy was 5.3 per cent in his series. No pressure signs were present in any of these cases. It has been our practice to recommend encephalography in all adult epilepsies. The more frequently we resort to this examination the higher we find the percentage of organic causes for convulsions, occasionally we find a case appropriate for surgical therapy.

Jacksonian motor or sensory attacks beginning after 30 years of age are more likely to be caused by tumor. Any focal attack followed by motor weakness or sensory changes and increased reflexes should be explored surgically whether pressure signs are present or not. Often a slightly increased manometric reading will be found on spinal puncture. If there is doubt, encephalography definitely decides, by giving information not obtainable by any other diagnostic method. Bailey and Cushing⁹ in their studies of gliomatous tumors called attention to occasional jacksonian epilepsies of long duration in cases of cerebral astrocytomas. They reported two of these relatively benign tumors that did not show pressure symptoms.

Fincher and Dowman¹⁰ in a study of 130 patients with jacksonian epilepsy found brain tumor in thirty-two. Of these, twelve, or 37.5 per cent, gave no evidence of increased intracranial pressure. These authors state "This statistical fact is of particular value since it emphasizes the possibility of intracranial neoplasm in cases presenting evidence of localized neurologic manifestations without symptoms and findings of general increased intracranial pressure."

Psychic manifestations are often the first symptoms in brain tumor, particularly in the tumors located in anterior portions of the cerebrum. Jameison and Henry¹¹ in a study of twenty-six psychotic patients in whom brain tumor developed found that in about one third of the cases a well developed psychosis had been

recorded before there was any indication of the tumor. The cerebral neoplasm was diagnosed before death in only 30 per cent of these cases, illustrating the need for more careful study of the etiology of atypical mental states. The psychic reactions accompanying brain tumor, though often so variable as to be of little value in localization, in the absence of other etiologic factors often serve as clues to the diagnosis of the tumor, especially if the psychotic reaction is of an organic type. A frontal lobe syndrome with change of personality (affective change), impairment of mental retention and mental activity and loss of insight should cause one to suspect tumor in cases in which cerebral arteriosclerosis and syphilis can be ruled out. In the absence of pressure phenomena, encephalography is indicated to confirm the diagnosis.

One of the most confusing diagnostic problems in cerebral neoplastic disease is the differentiation between vascular thromboses, softenings and invasive tumors without manifest pressure phenomena occurring during the sclerotic age. The diagnosis is further complicated by the combined pathologic changes of neoplasm and cerebral vascular softening or hemorrhage. Pressure signs are latent because the increased size of the tumor is compensated by the diminution in size of the senile brain and the degeneration of a large amount of brain tissue, so that the total intracranial contents are not above normal.

Bickel and Frommel¹² found in forty cases of death caused by brain tumor that six cases had been diagnosed as vascular softening and tumor was not suspected. The course of the disease with successive apoplectiform attacks was short in these patients, all more than 60 years of age. None of these six patients had increased pressure signs.

Riley and Elsberg¹³ report four similar cases, all infiltrating gliomas with cerebral degeneration, which did not show increased intracranial pressure. They believe that in these cases a diagnosis must be made ante mortem by diagnostic puncture or ventriculography.

Globus and Strauss¹⁴ reported seven cases, about one of which, a spongioblastoma, they stated that the clinical manifestations were indistinguishable from those of vascular lesions and that the tumor could be identified during life only by ventriculography.

Wechsler and Gross¹⁵ reported seven cases of brain tumor in which diagnoses of vascular or degenerative lesion were made.

Surgery in the group of malignant gliomas without pressure is particularly discouraging, since destroyed brain tissue cannot be restored and a more extensive defect is likely to follow surgical intervention. With the aid of encephalography and experience, perhaps some of these malignant gliomas can safely be declared inoperable. Failure of such cases to respond to dehydration therapy, involvement of the speech center, and rapid progression of symptoms are definite contraindications to operation.

The following group of tumor cases presented interesting diagnostic problems with an absence of increased intracranial pressure phenomena. In the majority of cases encephalography gave valuable confirmatory information.

REPORT OF CASES

CASE 1—*A large inoperable glioblastoma multiforme, no pressure phenomena, diagnosis proved by encephalography, death within one year*

R C, a man, aged 39, an airmail pilot, examined, Sept 28, 1932, had for several months noted a slight slowing up in the efficiency tests of the airmail service. About August 1 he first noted attacks of numbness of the right foot and leg. These attacks increased, involving the right hand and producing transient ataxia with momentary blurring of consciousness. About September 20, a major generalized seizure occurred.

The initial complete neurologic examination was entirely negative. Cisternal puncture showed a pressure of 4 mm of mercury, 4 cells per cubic millimeter with normal serologic constituents.

The patient was admitted to the hospital for encephalography, October 4. While under the effects of morphine and scopolamine preliminary to air injection a convulsion was witnessed. The spasm began in the right foot, focal at first, but quickly spread bilaterally in a generalized seizure. A transient weakness of the right seventh nerve, right arm paresis with right ankle clonus, extensor plantar reflex and hypalgesia of the entire right side were observed.

Encephalographic examination after the introduction of 125 cc of air revealed that the right anterior horn was normal in size but was displaced from 6 to 8 mm toward the right. No air was seen in the left lateral ventricle. There was obliteration of the subarachnoid spaces over the left cortex. The interpretation was a partial block of the foramen of Monro on the left side due to tumor in the left parietal region.

An exploratory operation performed by Dr W McK Craig at the Mayo Clinic revealed a soft mass at a depth of about 3 cm in the left parietal lobe. No tumor tissue was found on aspiration. Convalescence was stormy. The patient became aphasic and had a right hemiparesis following the operation, but this gradually improved. Severe convulsions recurred at intervals, high voltage roentgen treatments were given, but the patient died about nine months after operation from medullary compression.

Necropsy revealed a large tumor mass in the left medial parietal region with considerable necrosis and indistinct separation from brain tissue.

The diagnosis was glioblastoma multiforme.

CASE 2—*A large meningioma showing only local pressure phenomena, diagnosed by x-rays, complete removal and recovery*

Mrs P D, aged 50, was examined, May 15, 1933. In October 1932 the patient first noted attacks of cramping of the right foot. After several such attacks there occurred clonic spasm of the entire right half of the body without loss of consciousness. After a free interval of about six months the attacks recurred. There were no other complaints.

Complete neurologic examination revealed only a slight paresis of the right lower face and arm. A cisternal puncture showed a pressure of 6 mm with normal cellular and serologic changes in the fluid.

Roentgen examination of the skull showed a prominent diploe over the left parietal region and a thin layer of calcification along the falx in the midline region. A faint shadow measuring 2 by 3 cm was seen in the left superior parietal region.

Encephalographic studies after the removal of 120 cc of fluid revealed a shift to the right of about 6 mm, and the left lateral ventricle was shifted downward about 3 mm. There was flattening and depression of the posterior half of the anterior horn of the left lateral ventricle. The third ventricle was enlarged. No air was seen in the left cortical subarachnoid spaces, and only a moderate amount was seen over the left cortex. The interpretation was a space-consuming lesion of the left parietal frontal region, particularly parietal, probably a meningioma.

A left parietal exploration was performed by one of us (J J K). There was no increase in intracranial pressure. Over the left superior parietal region, about 2 to 3 cm from the superior sagittal suture, a tumor measuring 5 by 6 cm was found beneath the dura. The tumor was firmly attached to the dura and adherent to the cortex beneath. The tumor was completely removed with about 2 cm of the dura.

The diagnosis was meningeal fibroblastoma, parasagittal.

The patient made a normal recovery with a slight residual right facial and arm weakness remaining for a time.

CASE 3—*A probable glioblastoma multiforme, diagnosed by encephalography, inoperable, death within six months, general ized pressure signs in the terminal stages*

Mrs C K M, aged 41, seen, April 4, 1932, complained of fatigue and was slightly lethargic. In December 1931, following a head cold treated as sinusitis a dull, aching pain developed over the left eye. This pain increased in severity during March and the patient's husband (a physician) noted that she had a slight right lower facial weakness on smiling and some trouble in recalling names, with memory lapses.

A complete neurologic examination revealed only a lower right facial weakness and a slight paraphasia. A cisternal puncture showed pressure of from 4 to 6 mm of mercury with normal cellular and serologic constituents in the fluid.

Roentgen examination of the skull showed a suggestion of pressure markings in the left frontal region and a small area of bone rarefaction in the anterior left temporal region.

Encephalography after the removal of 175 cc of fluid revealed that the right lateral ventricle was about six times the normal size. The left lateral ventricle showed an encroachment on the middle portion of the floor adjoining the midbrain. There was a rounded tumor mass about 3 by 4 cm in diameter below the left lateral ventricle. The right border extended across the midline from 10 to 15 mm. An irregular elevation from the floor of the left lateral ventricle about 11 cm anterior to the junction between the anterior and inferior horns nearly separated the ventricle into an anterior and posterior division.

A left frontal exploration was carried out by one of us (J J K). No increased intracranial pressure was found and no definite tumor was detected.

High voltage roentgen treatments were given. The patient gradually became more aphasic and mentally confused. In June the first signs of generalized increased intracranial pressure appeared. The patient died. Necropsy was not performed.

CASE 4—*A clinical diagnosis of traumatic hematoma or cyst proved to be an oligodendroglioma, recurrence after removal, death two years later*

W S, a man, aged 28, examined, Oct 15, 1932, had fallen about 20 feet, from a scaffold in October 1929. He was unconscious about one hour and hospitalized for one week at the time of the accident. In March 1930 left-sided sensory and motor spasms began, starting in the left thumb and fingers, followed by tonic spasm of the hand, and ending in unconsciousness. These attacks soon occurred daily but were partially relieved by continuous ingestion of phenobarbital. The patient had noted a few headaches since the accident.

A complete neurologic examination revealed no focal signs. The spinal fluid pressure was 10 mm of mercury with normal cellular and serologic changes.

Encephalographic studies after removal of 100 cc of fluid revealed a moderate obliteration of the subarachnoid markings over the right cerebral hemisphere with compression and slight displacement of the right lateral ventricle to the left. The interpretation was a pressure lesion in the region of the right motor area. The clinical diagnosis was a delayed subdural hematoma or cyst.

Exploration over the right motor area by one of us (J J K) revealed flattened convolutions and pressure obliteration of the subarachnoid spaces. There was a focal lesion of the motor cortex with vascular and fibrous attachments of the arachnoid and dura, with old thrombosis of the cortical vein and a definite fibrous scar in the cortex beneath, measuring about 1 cm in diameter. The cortex beneath this area felt soft and degenerated. Faradic stimulation of the scar caused a sensation and movement in the left thumb similar to the onset of an attack. Stimulation of the normal motor cortex above this caused

movement of the entire arm. The scarred area, 3 cm in diameter, was excised. A decompression opening was made in the temple and the wound was closed.

The cellularity of the tissue with the uniformity of cell size and lack of intercellular substance corresponded to an oligodendrogloma of a rather rapidly growing type.

A slight residual weakness of the left hand with hypalgnesia followed the operation. The patient received a course of high voltage roentgen therapy and returned home. The convulsive seizures progressed and the patient died in the fall of 1934, not under our observation.

CASE 5—Treated for epilepsy about ten years; no generalized pressure signs, probable clinical diagnosis meningioma, pathologic diagnosis malignant oligodendrogloma; recurrence after removal, died eighteen months later.

J. A. H., a man aged 54, examined July 28, 1930, had first begun having generalized convulsions at about the age of 43. For a number of years he had been treated for epilepsy by a neurologist. During the past year the spells had become more severe and the patient had noted memory loss with some trouble in understanding and in expressing himself. There had been only very slight headache in the upper cervical region for two weeks.

Complete neurologic examination revealed a word naming aphasia, a word reading aphasic reaction and a right homonymous hemianopsia. A cisternal puncture showed a pressure of 8 mm of mercury with normal cellular and serologic constituents.

Roentgen examination of the skull showed a calcified area 5 by 6 cm in the left temporoparietal region.

An exploration by one of us (J. J. K.) over the left inferior parietal area revealed some calcified plaques in the temporal dura. A tumor about 4 cm in diameter was found adherent to the dura. It was soft and vascular with no apparent capsule, and was completely removed. There was considerable troublesome bleeding.

The diagnosis was oligodendrogloma.

The patient made a good recovery with some residual hemianopsia and right leg and right arm weakness, which gradually improved under high voltage roentgen therapy. He became worse after eighteen months and died in April 1932.

CASE 6—A roentgen and clinical diagnosis of cerebral cyst proved to be a benign oligodendrogloma six years after focal spasms without generalized pressure signs, recovery following surgical removal of tumor.

G. McK., a boy, aged 8 years, examined Aug. 17, 1931, had complained for six years solely of attacks of stiffness in the arms, legs and neck, lasting a moment and followed by transient flaccid weakness of the right arm. There was never complete loss of consciousness, the attacks occurred in serial form every few months at first, they became more severe later, with complete normality in the free intervals.

A complete neurologic examination was entirely negative but during observation a seizure occurred. The arms and neck were rigid, the right arm was straight and the left flaccid. There was a slight tremor, the legs were immobile. The patient stared but was conscious and the attack lasted only a minute. Immediately following the attack the right arm and face were paralytic for a minute but there was no disturbance in reflex activity or sensation.

A spinal puncture showed pressure of from 6 to 8 mm with normal cellular and serologic constituents.

A roentgenogram of the skull showed a rather smooth defect in the inner table of the medial portion of the left parietal bone, about 3 cm in diameter. Prominent digital markings were present in both parietal and frontal regions. There was some increase in density over the parietal region with one large area of lessened density 1 inch in diameter toward the vertex which would suggest some bone destruction of the inner table in this area.

The interpretation was evidence of some old increase in intracranial pressure and a questionable defect in the vertex portion of the left parietal bone, suggesting meningioma. The clinical diagnosis was cerebral cyst.

An exploratory bone flap done by one of us (J. J. K.) revealed a rather tense dura that felt cystic in the medial

parietal region. The needle struck 5 cc of clear fluid at a depth of 2 cm. When the dura was opened a soft tumor in the medial posterior parietal region was found covered by thin edematous cortex. Silk sutures were placed deeply about surrounding blood vessels, the tumor was freed by blunt dissection and removed. It measured 4 by 5 cm, had no capsule and was too soft to keep intact.

The diagnosis was oligodendrogloma.

High voltage roentgen therapy was given and the patient was dismissed on the twelfth day in good condition. Since then there has been no evidence of recurrence and no return of epileptiform attacks. He is well and active, with normal neurologic manifestations.

CASE 7—A clinical picture simulating an enccephalitic infection with absence of pressure phenomena traced at necropsy to be a malignant astroblastoma.¹⁰

H. S., a girl aged 8 years was referred to Dr. J. A. Henske Oct. 20, 1930, with evidence of a progressive chorea with asthemia for about three months. At the initial examination the condition appeared to be quite typical of acute infectious chorea. November 15 a complete neurologic examination by Dr. G. A. Young revealed vertical nystagmus on upward gaze, bilateral ataxia of the arms and legs involving the left side more than the right, involuntary choreiform movements, in absence of the left abdominal reflex, left ankle clonus and an extensor plantar reflex. In the Romberg position the child deviated to the left. All forms of sensation were normal.

Several spinal fluid examinations never showed pressure above 10 mm of mercury. The optic fundi were always normal. There were occasional febrile reactions, with leukocytosis up to 17,800. The entire picture suggested an infectious process. The diagnosis at this time was a chronic encephalitis, with mid-brain, bulbar, pontile, cerebellar pathway involvement.

A progressive stupor developed and bilateral pyramidal tract signs and bulbar involvement were noted in the terminal stage. The child died, Feb. 14, 1931.

At necropsy the external appearance of the brain was essentially normal. On the left side of the pons was a tumor which caused it to bulge somewhat and become flattened and spread out, owing to pressure against the base of the skull. This area measured 4 by 3 by 2 cm and was closely adherent to the surrounding tissue. The tumor was white, rather firm, and more or less uniform in gross appearance. Adhesions extended backward to the cerebellum. The lateral ventricles were markedly dilated on both sides and in about equal amounts. The third ventricle also was dilated widely and contained a large amount of clear fluid. The tumor extended well into the pons, involving an area nearly 3 cm in diameter. There was a marked pressure furrow of the foramen magnum.

The diagnosis was astroblastoma.

CASE 8—A malignant glioblastoma multiforme, recurrent, apoplectic attacks simulated vascular disease until spinal pressure of 16 mm led to diagnosis by encephalography, recurrence after removal, death within one year.

Mrs. A. S., aged 46, was examined, Oct. 11, 1928. Eight weeks before, a left hemiparesis had developed within a few hours. Under hospital observation the patient made a good functional recovery within two weeks. One week later, after exertion, the patient again lost the use of the left half of the body and focal left sided convulsive seizures occurred at intervals.

The general physical and neurologic examinations were negative except for left hemiparesis with pyramidal tract reflex signs and some hypalgnesia. The blood pressure was not increased.

Roentgen examination of the skull revealed some shadows of increased density in the right frontal area.

The patient had no generalized intracranial pressure symptoms or signs until after an encephalogram one month after admission, when haziness of the optic disks appeared. The first pressure sign was 16 mm of spinal fluid pressure. This finding raised the first suspicion that the apoplectic syndrome was probably caused by a neoplasm and led to the use of encephalography.

¹⁰ We are indebted to Dr. J. A. Henske for the privilege of reporting case 7.

CEREBRAL NEOPLASMS—BENNETT AND KEEGAN

JOUR. A. V. A.
JAN. 5, 1935

Encephalography showed poor filling of the right anterior horn with a shift of the ventricle to the left from a filling defect in the midportion of the ventricle. The interpretation was a subcortical tumor of the right parietal lobe.

December 17, a right superior parietal exploration was made by one of us (J. J. K.) and 50 cc of straw colored fluid was removed near the anterior horn of the right ventricle at a depth of from 3 to 4 cm. In the temporal subarachnoid space in the region of the lateral cerebral fissure was an old basilar subarachnoid hemorrhage. The tumor, about 3 cm in diameter, was found in the parietal lobe. The surface was firm and well defined, in the deeper portions it appeared soft and degenerated. It was enucleated, the corpus callosum was seen in the floor of the cavity.

The tumor removed at operation weighed 52 Gm., was soft, friable and hemorrhagic, with no capsule. Microscopic sections showed densely massed moderately small cells with little stroma. The tumor cells in well preserved areas were rather uniform in size, with numerous mitotic figures. Other areas showed necrosis and hemorrhage from rupture of numerous thin walled blood vessels.

The diagnosis was glioblastoma multiforme. An aseptic meningitis followed the operation with a spinal fluid pleocytosis. Roentgen therapy was given to the patient, who made a good functional recovery for six months. In May 1929 a recurrence of the left hemiparesis occurred. A large amount of cystic fluid was aspirated but a convulsive state followed, and the patient died, July 24, 1929, of medullary compression.

At necropsy a large protuberant mass was fixed to operative adhesions in the right parietal region. The diagnosis was glioblastoma multiforme without generalized pressure signs diagnosed by encephalography death within nine months.

CASE 9—A malignant glioblastoma multiforme without generalized pressure signs diagnosed by encephalography death within nine months. J. H., a man aged 35, was examined at the University Hospital, May 4, 1929. In February 1928 the patient had been refused life insurance on account of glycosuria and diabetic spells, asthenia and spasmodic jerking of the right arm and leg. Under hospital observation at this time blood sugar readings were as high as 233 mg per hundred cubic centimeters. The neurologic examination was negative. A tonsillectomy was performed and he was dismissed on a diabetic regimen.

The patient was readmitted, August 20, on account of progressive weakness of the right half of the body with some occipital headache. Examination at this time disclosed a slight right hemiparesis with absent abdominal reflexes but no other pyramidal tract signs. Spinal puncture showed 10 mm of mercury pressure and three days later the pressure was 14 mm.

The patient was becoming somewhat somnolent. Encephalographic studies were then carried out, which revealed a filling defect of the left lateral ventricle, with the right ventricle dilated and the ventricles shifted to the right. The clinical and roentgenologic interpretation was a probable subcortical glioma in the left postcentral region.

A left parietal craniotomy operation by one of us (J. J. K.), September 18, revealed a very tense dura and lack of normal resistance to the exploring ventricular needle, and 5 cc of thick yellow fluid was released at a depth of 3 cm. In view of the tension, depth and probable malignant character of the tumor in the left parietal lobe, further exploration was not done. The patient's condition gradually became worse following operation and he died, November 11.

Necropsy disclosed flattened cerebral convolutions and a tumor, about 5 cm in diameter, deep in the left temporoparietal region. A diagnosis of glioblastoma multiforme was made.

CASE 10—An inoperable craniopharyngioma, with general pressure signs lacking simulated on infectious encephalopathy diagnosed by encephalography death ten months after onset. M. J. O., a man, aged 39, in February 1932 was confined to bed one week with influenza, during which time he was drowsy and apathetic and had double vision. His strength was never

17 We are indebted to Dr. A. W. Adams for the final notes in this case.

fully regained and gradually failing vision was noted. Since July the patient had been unable to read. Dr. W. H. Stokes at this time found the vision 20/40 in both eyes, the visual fields and fundi were normal with a slight vertical nystagmus. In August all work was stopped and the vision was reduced to 20/200 in each eye. The fields then showed central scotomas with involvement of the blind spot and a sector defect for color in the lower part of the right nasal field and the lower part of the left temporal field. The results of examination seemed to be in keeping with retrobulbar neuritis. The patient's complaints at this time were fatigue, poor vision, memory failure and low-grade fever.

Repeated neurologic examinations revealed no focal manifestations. Cisternal puncture showed a pressure of 4 mm of mercury, normal cell count, normal protein content, and a negative Wassermann reaction. The colloidal gold curve was 1122110000. A tonsillectomy was performed, following which there was a prolonged fever until October. The lethargic state and mental confusion progressed. By September the vision was reduced to 7/200 and 9/200 and a definite pallor of the temporal halves of the optic nerves was present. The sinuses were explored but no definite infection was discovered. Neurologic examinations were still negative except for the eyes. In September the spinal pressure was 4 mm of mercury, the protein content was increased, but otherwise the fluid was normal. The mental deterioration was becoming profound.

The general impression of the examiners was that the cerebral disorder was most likely a toxic or inflammatory encephalopathy. The patient then stuporous, was taken to the Mayo Clinic in December 1932.

A diagnosis of indeterminate brain lesion was made and encephalography carried out. This suggested a prechiasmatic lesion, probably basofrontal. A right frontomotor exploration was carried out. On elevation of the frontal lobe the optic nerves and chiasm were found to be involved in an inoperable tumor mass which seemed to extend from the third ventricle anteriorly. Death followed within twenty-four hours. At necropsy there was found a large infiltrative invasive cystic tumor of the third ventricle, growing forward and involving the optic chiasm and nerves. The microscopic appearance of the tumor corresponded to a cystic adamantinoma of the floor of the third ventricle.

CASE 11—Parasagittal meningioma, no generalized pressure signs, diagnosis confirmed by x-ray, complete recovery following removal.

H. O., a man, aged 40, seen, Feb. 16, 1933 at the Nebraska Methodist Hospital, gave a history of attacks of numbness and later weakness in the left foot, beginning in January 1931. Recently he had developed epileptiform attacks involving the left side of the body with residual left sided spastic weakness persisting between attacks. He had no headaches, nausea or vomiting.

The neurologic examination showed a left hemiparesis of the spastic type, greater in the leg than in the arm, with very little sensory loss. The spinal fluid pressure was 4 mm of mercury and the serology was negative. There was no papilledema or impairment of the visual fields.

A roentgenogram of the skull revealed an area of hyperostosis in the right superior parietal region with an underlying intracranial mottled calcification about 2 cm in depth and 3 cm in diameter. The parietal diploic venous channels were accentuated on both sides, more on the left.

A diagnosis of right parasagittal meningioma was made and a right parietal craniotomy performed by one of us (J. J. K.), March 4, 1933. Owing to considerable hemorrhage in elevation of the bone flap, a two stage operation was decided on and the dura was not opened. Following this operation signs of intracranial pressure appeared, partly relieved by hypertonic dextrose intravenously. Second stage operation was performed, March 11, and a large firm, encapsulated tumor was removed from the right medial parietal region. Microscopic sections showed the tumor to be a rather dense fibrous type of meningioma.

The postoperative recovery was satisfactory with considerable edema of the brain and herniation for a few days and increased paralysis of the left side for a time, but gradual

improvement occurred with relief from pressure and only slight residual spastic disability of the right foot remained

CASE 12 — Case illustrating difficulties in differentiation between epidemic encephalitis and third ventricle tumor

M. E., a boy, aged 9 years, admitted to the University Hospital, March 7, 1934, had begun to complain of diplopia and lethargy in school about four weeks before. In about one week weakness of the right half of the body began and developed to hemiparesis. Just before admission the lethargy and asthenia became progressive. There was no history of headache or febrile infection.

Complete examination disclosed a complete left third nerve palsy, double fixed pupils, a right hemiparesis with pyramidal tract reflexes, a slow pulse and coma from which the patient could be aroused momentarily to cooperate. Spinal puncture showed 6 mm of pressure, 7 cells per cubic millimeter, normal protein content and 54 mg of sugar per hundred cubic centimeters. A second puncture twelve hours later showed 4 mm of pressure with normal constituents of the fluid.

The patient was treated on the basis of an infectious process. Forced spinal fluid drainages were carried out with hypotonic saline, about 200 cc of fluid was removed at a drainage. There was no improvement in symptoms, the only change in the spinal constituents was an increase in cells and protein content with a colloidal gold curve reading of 3333322100. The temperature ranged from 100 to 105 F most of the time.

The patient died with a terminal hyperpyrexia of 110 F on March 22.

Necropsy revealed a grossly circumscribed lesion, apparently a soft yellowish invasive tumor completely surrounding the third ventricle. There was no block, the lateral ventricles measured about twice the normal size, the tumor 3 by 5 cm.

Sections of the midbrain region in which extensive necrosis gave the gross appearance of tumor with a rather sharply defined border showed no definite tumor tissue. Large areas of complete necrosis were bordered by extensive mononuclear cell tissue and perivascular infiltration with many endothelial macrophages, in some places almost occluding the lumen of blood vessels, and bordering degenerated areas filled with chromatin particles.

The diagnosis was acute epidemic encephalitis with necrosis.

COMMENT

In none of these twelve cases was the characteristic triad of generalized increased intracranial pressure present. None of the cases presented fundoscopic changes of the pressure type. In only two instances was the spinal pressure reading above 10 mm of mercury during our diagnostic observation period. One patient had a pressure of 14 mm and another had a pressure of 16 mm, giving the first indication of a pressure lesion. Headache was noted in only two instances and in these increased pressure was a doubtful cause. Vomiting was not present in any case during the diagnostic observation period.

The most valuable single early diagnostic symptom or sign was focal spasms. In eight cases jacksonian seizures were present. One patient had been treated for an essential epilepsy for about ten years. The earliest symptom in one case was a sensorium change, in one case, progressive blindness, in another, progressive choreiform movements, in one, recurrent hemiparetic attacks along with focal spasm, and in another case, lethargy with diplopia.

In six cases (50 per cent) the roentgen examination showed localized changes suggestive of localized pressure with other conditions suggestive of an intracranial neoplasm. In seven cases encephalographic studies were made and considered diagnostic of tumor with accurate localization in each instance. Four of these cases presented marked distortion, compression and displacement of the lateral ventricles, indicating large tumors, but there was no definite increase in the intra-

cranial pressure. In two cases roentgen studies of the skull were not made.

In nine cases we made a diagnosis of cerebral neoplasm in the absence of generalized intracranial pressure phenomena. In three instances a diagnosis of inflammatory encephalopathy was considered more likely. In case 10 the correct diagnosis of tumor was made later in another clinic by encephalography. In an 8 year old child (patient 7) the tumor was not suspected but was found at necropsy. In another child (patient 12) a typical syndrome of lethargic encephalitis was present. At necropsy gross examination revealed what was apparently a third ventricle tumor, but the histologic report was encephalitis. Two tumors in the region of the third ventricle presented the greatest diagnostic difficulties in this group because of the febrile disorder, the short duration of the illness and the complete lack of pressure phenomena.

There were three excellent functional recoveries in the group, and three instances of palliative relief for several months from decompression and partial removal. Of the fatal cases, five patients with a highly malignant glioblastoma multiforme died within one year after the onset of symptoms. In two cases, oligodendrogliomas recurred and death occurred within two years. One patient is still alive and in good health three years later. One patient with craniopharyngioma died within ten months. Two of the three recoveries were in patients with benign meningiomas.

CONCLUSIONS

1 The classic cardinal symptoms of increased intracranial pressure are lacking in from 15 to 30 per cent of patients with cerebral neoplastic lesions.

2 The size of the neoplasm has little to do with the production of intracranial hypertension. The location of the tumor has much more to do with the degree of hypertension present.

3 The spinal manometer is a more accurate guide in the diagnosis of a pressure lesion than the fundoscopic examination.

4 Localized pressure phenomena in certain cases are highly diagnostic before generalized pressure symptoms appear. Some of these local signs are the results of roentgen examinations, epileptiform seizures, especially focal spasms and organic psychotic reactions.

5 In certain cases a clinical differentiation cannot be made between vascular lesions, thrombotic or hemorrhagic, and cerebral neoplasms, especially the "spongionomas." In these cases encephalography is the only accurate diagnostic method in which pressure signs are absent. Rapid progression of symptoms with involvement of the speech center, a large defect shown on encephalography with an absence of intracranial hypertension and no improvement on dehydration all indicate an inoperable type of glioma. With these criteria one should be able to prevent unnecessary surgical exploration.

6 Tumors in the region of the third ventricle, especially in children, simulate infectious encephalitic disease, run a short febrile course and at times show no pressure signs. In these cases a positive diagnosis could probably not have been made even with encephalography.

SUMMARY

In twelve cases of cerebral neoplasm, generalized intracranial hypertension was absent. In ten cases the diagnosis was correctly made before pressure signs

were manifest. The results of encephalographic examination confirmed the diagnosis in seven instances. We believe that various diagnostic methods should be used more generally to make earlier diagnoses of brain tumor in doubtful cases.

1204 Medical Arts Building

ABSTRACT OF DISCUSSION

DR ALFRED W. ADSON, Rochester, Minn. This paper emphasizes the importance of making an early diagnosis in cases of tumor of the brain and calls attention to mechanical means that have proved of value in arriving at a proper diagnosis. The disturbance of intracranial pressure by encephalography can result in a fatality; therefore such an examination should be performed in an operating room where there are facilities for immediate craniotomy. Although encephalography supplies much information concerning the size and contour of the convolutions, subarachnoid spaces and the ventricles, I do not believe it should be used indiscriminately, nor should it be used in cases in which the history and clinical observations clearly indicate the situation of the lesion, since the procedure is painful, requires hospitalization of the patient, and incurs unnecessary expense.

DR LLOYD H. ZIEGLER, Albany, N. Y. Tumors that grow slowly in adults and do not occlude the foramina of Monro, Magendie and Luschka or the aqueduct of Sylvius may attain a large size without producing choked disks or other evidences of intracranial pressure. Intracranial adaptations to slow growing neoplasms are remarkable by the relative absence of symptoms. In children, before the cranial sutures have united, intracranial growths may not produce, until late, the usual clinical pressure symptoms. The authors report one case of astroblastoma of the pons in a child, aged 8 years. This tumor usually occurs in the cerebral hemispheres. I wonder if this could have been a spongioblastoma, which is more likely to be found in the brain stem in children. It is a well known fact that, despite its proximity to the aqueduct of Sylvius and the third ventricle, a neoplasm of the pons produces intracranial pressure late in its course. It is almost impossible at times to differentiate between encephalitis, neoplasm and vascular lesions. In fact, neoplasms may occlude or erode blood vessels to complicate the picture. In every patient who has otherwise unexplained convulsions or petit mal attacks, brain tumor should be suspected. A transient sensory or motor disturbance in an extremity must be explained, usually by some alteration in brain physiology which includes the possibility of neoplasm. Unless one has had much clinical neurologic experience, frontal tumor syndromes may be erroneously disposed of as premenstrual psychoses, psychoses associated with arteriosclerosis, or even depressions or involutional melancholia. A change in personality without corroborative evidence is not sufficient for diagnosing frontal tumor. The authors have stimulated neurologists to think more profoundly about the likely neuropathology and mechanism of intracranial lesions without pressure signs. As experience accumulates, it is doubtful whether encephalography would need to be employed so regularly, but its value is well brought out by the authors in difficult and puzzling cases.

DR GEORGE W. HALL, Chicago. This is an important subject and there are some practical things that should be noted in the discussion. In cases in which there is calcification of the pineal body, one can usually rely on the shifting of that body in making a definite diagnosis between vascular lesions and a tumor located in one or the other hemisphere. Naffziger called attention to this sign, namely, the shifting of the calcified pineal body to the opposite side in which the tumor was located. When one sees patients who show evidences of motor aphasia, for instance in right handed individuals, the shifting of the pineal body to the right is a sign that cannot be safely overlooked. I think it is well to emphasize again what was mentioned in the paper, namely, that one should be extremely careful in making a lumbar puncture in these cases, especially when the tumor is located in the infratentorial region.

DR TEMPLE FAY, Philadelphia. Drs. Bennett and Keegan should be congratulated on calling attention to the fact that 15 per cent of cases with intracranial neoplasm may show no signs of increased intracranial pressure. I have had to abandon the idea of "increased pressure" as an index of intracranial pathology. "Pressure" is the amount of force (in terms of physics) of one body of matter resisting or opposing another. "Pressure" is only an index of the apposition of forces. "Pressure" inside the cranial cavity represents the relationships of the contingent volumes, the volume of a tumor, gradually growing and expending itself against the volume of blood, the spinal fluid volume and the brain. If there is an equal shift of volumes, there is going to be no change in pressure. There may be a gradual shift of volume at the expense of a tumor or a collection of fluid but always at the expense of some other volume. Either the container must enlarge or some other component surrender its space. "Focal" or "general" symptoms appear when the volume shift is such that the brain cannot function locally or generally from the standpoint of its nutrition. If a knowledge of physics and hydraulics is applied and "volume" relationships are considered in correlation with clinical symptoms, one will find this "no pressure" mystery explained. In the terminal stages of eclampsia or edemas of the brain in which blood has been displaced gradually and equally, one finds low "pressures" with unconsciousness. High "pressures" frequently occur without symptoms. Cases cannot be compared on a pressure basis alone. Some attack has been made on the question of encephalography. I saw from a large experience that in careful hands, and with proper precautions, that procedure is safe and of extreme diagnostic importance. In this I concur with the authors.

DR W. J. GARDNER, Cleveland. I agree heartily with the authors as to the value of the mechanical aids they have described in intracranial diagnosis. I have used encephalography in well over 100 cases of expanding lesions in the brain, and I have used it regardless of the presence of choking of the optic disks. If choking of the optic disks is absent, the encephalograms are likely to be more satisfactory. When a choking of the optic disks is present, the ventricles will not be visualized in a certain proportion of cases. The precautions to be observed are simple. Encephalography should not be carried out when a surgical lesion is suspected unless the operating room is prepared for craniotomy as soon as the films are developed. Within an hour from the time the procedure is started the films are readable, and if a surgical lesion is present, and particularly if there is increased intracranial pressure, the operation should not be delayed. There is no question that once the spinal fluid is removed it tends to reaccumulate more rapidly, and that constitutes the danger in delaying operation. I have made encephalograms in nine cases of suprasellar tumor with very definite results in each case. In most instances the tumors were definitely outlined by the air in the subarachnoid space. In some of these cases, a diagnosis could not have been made by ventriculography because of the absence of ventricular distortion. Encephalography has disclosed several unsuspected subdural hematomas. Encephalograms are made in post-traumatic cases if the spinal fluid is the least bit yellow. Parasagittal meningiomas, of course, very frequently have no increase in the intracranial pressure and occur in the age when it is difficult to differentiate the lesion from cerebral vascular disease. There is some risk in performing encephalography in patients with arteriosclerosis. Even here, however, I believe that the advantages of the procedure outweigh the disadvantages. I feel that these mechanical aids are extremely valuable but should, of course, be used only when definitely indicated and then should be used unhesitatingly.

DR ALBERT S. CRAWFORD, Detroit. Those who are interested in neurologic surgery are grateful to the authors for presenting this subject, because such papers are increasing the general knowledge all over the country and bringing earlier diagnosis of brain tumors. As has been brought out, brain tumors may develop without the old, well recognized triad of headache, choked disks and vomiting. Because of such papers, there is an increasing suspicion among the diagnosticians for brain tumors. As a result, a larger percentage of cases are seen in time for early operation and hence more cures result. I agree

with Dr Adson that encephalography is a procedure that has danger in it but, on the other hand, it is being done safely in increasing numbers and I think with justification, especially in this group of cases. If encephalography is to be done, it should be done by one who is ready to take care of any complications that might arise. One variation I have been using in cases in which there may be trouble afterward is to make a preliminary occipital trephine, close up the skin and go ahead with the encephalography. If complications develop from obstruction in the posterior fossa, the trephine is ready and a needle can be quickly put into the ventricle and the pressure reduced without the delay of an operation. These cases constitute a group that may be called brain tumor suspects. There is developing an increasing suspicion that these cases may be brain tumors, and neurologists are now more commonly putting that down as a possibility. Previously brain tumor was one of the last things thought of by diagnosticians. Now it is put near the top of the list, and rightfully. It is by a more critical study of the "suspects" with a careful follow up, if at first negative, that continuing improvements in results can be hoped for.

DR WALTER ABBOTT, Des Moines Iowa. In the past two years I have seen three cases in the classification Dr Bennett has brought forth lesions of the third ventricle. One was a congenital defect and the other two were ball valve tumors. There were fluctuating symptoms and in all cases the spinal manometric readings were within normal limits. Encephalography was carried out and the ventricles were not filled satisfactorily, necessitating a secondary procedure ventriculography. As Dr Adson and Dr Crawford have mentioned I think that often in these third ventricle lesions although they are few in my experience, encephalography alone is not satisfactory.

DR A E BENNETT Omaha. The question of the indiscriminate use of encephalography has been brought up with which I agree. There is still fear of using encephalography in fourth ventricle tumors and other posterior fossa tumors. The only accident that I have had was in a ball valve third ventricle tumor in which an encephalogram was done and the patient died of cerebellar herniation a few hours afterward. I am fearful of that type of tumor. I agree with Dr Abbott that those tumors are difficult of diagnosis even with encephalography. Neurologists are going to see more and more of these tumor suspects earlier and should give increased attention to this subject. Everything available has had to be used to make an early diagnosis. I was glad to have Dr Fry bring out the relationship between the various brain volume states of edematous nature and obstructive lesions within the ventricular system. Some concepts in these situations will have to be revised if the mechanics of intracranial pressure is to be understood. I think Dr Gardner is even more courageous than we are in the use of encephalography in the diagnosis of his tumors, as illustrated in one of his cases in which they made a diagnosis of posterior fossa tumor by encephalography. We are afraid to go ahead in those cases as yet.

The Impersonal Attitude—Within the last few decades there has been a growing recognition that the disease has been overemphasized, that the patient has been somewhat neglected. Physicians with great experience and much human sympathy have been dismayed by the impersonal attitude of scientifically trained physicians who are so dehumanized that they treat their patients with the precision and the detachment with which they treat their experimental guinea-pigs and mice. Such an attitude may seem to bear the hallmark of science and therefore to be beyond criticism. This attitude toward the problems of medical practice may claim the authority of science only if science be very narrowly interpreted as being confined to the precincts of the laboratory and only if the actual phenomena of human nature be looked upon as outside the sphere of scientific observation. To do justice to his patient the physician must take into consideration not only the precise laws of the laboratory but also the laws which regulate the reaction of man to his environment even though these laws cannot be formulated in mathematical or precise physical terms.—Campbell, C Macfie. *Psychiatry from the Standpoint of the General Practitioner, Pennsylvania M J* 38 59 (Nov) 1934.

A A WEINSTEIN, MD
BOSTON

Our purpose in this communication is to summarize our experience during the last eighteen months in treating seventy-five patients with chronic heart disease by removing the entire normal thyroid gland.¹ Our efforts have been directed in five main directions: (1) clinical appraisal of the therapeutic value of the procedure,² (2) establishment of criteria for the proper selection of patients, (3) reduction in the risk of operation through study of the surgical technique and the best possible preoperative and postoperative care,³ (4) study of the mechanisms whereby the development of hypothyroidism results in relief of angina pectoris and congestive failure,⁴ (5) investigation and control of the secondary consequences of the hypothyroid state.⁵ Although final conclusions concerning these problems await the results obtained over a period of years, it may be helpful to state the results based on our present experience.

The group of seventy-five patients with chronic heart disease which forms the basis of this report was carefully selected from a much larger number of patients with heart disease treated at the Beth Israel Hospital. No patient showed any of the clinical signs or symptoms of thyrotoxicosis. Only patients found to have unquestionably normal thyroid glands by our pathologist Dr Monroe Schlesinger are included in this report. Most of the patients were chronic invalids confined to bed and chair existence. Other patients regularly suffered congestive heart failure when they undertook effort or showed attacks of angina pectoris at rest or on slight or moderate exertion. Every patient had been incapacitated for long periods in spite of having received all available medical therapeutic measures. Their clinical course was such that any

striking improvement could be definitely attributed to the operative procedure. Patients received the usual medical treatment for heart disease in the hospital for from weeks to months before operation to reduce the operative risk to a minimum. Patients were operated on in the presence of signs of congestive failure only.

after protracted medical treatment had failed to produce any further improvement.^a Operation on such patients is not advised.

RESULTS IN PATIENTS WITH CONGESTIVE FAILURE

Of the seventy-five patients with chronic heart disease, fifty patients were treated primarily for recurrent congestive failure of rheumatic, arteriosclerotic, hypertensive, congenital or syphilitic etiology (table 1). The ages of the patients ranged from 18 to 69 years, twenty-four were males, twenty-six females. The post-operative improvement in our patients has been judged by the loss of edema at rest or its failure to reappear on exertion, by diminution in pulmonary congestion as evidenced by disappearance of hydrothorax or râles, by the disappearance of orthopnea, by the diminution of cyanosis, by the increased capacity to undertake work, by the absence of dyspnea on moderate exertion, and by functional tests which are to be elsewhere described. Twenty-four of these patients have maintained compensation and have shown decided improvement for from two to eighteen months. For the first time in from months to years they are up and about the entire day without discomfort and without reappearance of the signs or symptoms of congestive failure. Four patients are able to undertake only light work, while twenty patients are living a life of moderate activity, and, although not indulging in heavy labor, many are economically rehabilitated. In more than

half of these patients the postoperative period ranges from six to eighteen months, eight have maintained their compensated state for more than a year. Case 1 is given as representative of this group of twenty patients (table 2) who are economically rehabilitated.

CASE 1—*Arteriosclerotic heart disease, rheumatic heart disease, congestive failure for three years, angina pectoris, marked improvement eighteen months after operation.*

G F, a man, aged 52, a chef, entered the hospital complaining of shortness of breath, palpitation and substernal pain of three years' duration. Three years prior to admission, while working, he suffered an attack of severe precordial pain which radiated down both arms. Despite several months of rest in a sanatorium, dyspnea and substernal pain were experienced on exertion. For two years before admission he had increasing edema of the legs. For nine months the patient was completely bedridden because of congestive failure and angina pectoris. Physical examination showed orthopnea, cyanosis, marked enlargement of the heart, auricular fibrillation and a mid-diastolic murmur at the apex. The liver was enlarged and tender, there was pitting edema of the legs and sacrum and moist râles at the bases of the lungs. The basal metabolism was minus 2 per cent, and arm to tongue circulation time was 44 seconds. These signs of congestive failure diminished after further treatment but did not disappear completely.

Total ablation of the normal thyroid gland was performed Dec 15, 1932. The basal metabolism had decreased to minus 28 per cent four weeks after operation. The patient was able to undertake moderate exercise without recurrence of signs and symptoms of congestive failure or angina pectoris. Three and one-half months after operation he was given work in the hospital as a porter in the research laboratories, working eight hours a day, six days a week. One and a half years after operation the patient was still at work full time. Physical examination revealed no sign of congestive failure, the patient complained of no dyspnea or precordial pain on exertion. The basal metabolism was minus 26 per cent, the arm to tongue velocity was 42 seconds.

The patient with arteriosclerotic and rheumatic heart disease, angina pectoris and congestive failure of three years' duration has shown conspicuous improvement for one and a half years after operation. He shows no evidence of congestive failure and at no time has he had dyspnea, palpitation, pain in the chest or edema while at work. In spite of the permanent lowering of the metabolic rate and the development of mild unprogressive symptoms of myxedema, he has shown none of the mental slowness usually associated with severe spontaneous myxedema. He is carrying out his work satisfactorily and, mentally, is a normal person.

Of the twenty-four patients with congestive failure who have maintained their improvement, four are able to undertake only light work. The average duration of postoperative improvement in these four patients is seven and one-half months.

Two patients have shown little or no improvement following operation. The clinical abstract of case 16 is illustrative of this group.

CASE 16—*Arteriosclerotic heart disease cardiac failure of three years' duration, bronchial asthma, pulmonary emphysema, angina pectoris, no improvement eleven months after operation.*

W B, a man, aged 64, admitted to the Beth Israel Hospital, June 13, 1933, complained of shortness of breath and swelling of the legs. In 1929 he was unable to walk more than a block because of dyspnea. During the years 1929-1933 he was admitted to hospitals five times for congestive failure. In May 1932 several attacks of substernal and precordial pain developed, radiating to the back and to the left arm. On admission, physical examination revealed a rigid thorax with increased anteroposterior diameter. The lungs were hyperresonant, with numerous ronchi and many coarse râles at both bases. The liver was moderately enlarged. There was pitting peripheral edema. Basal metabolism was minus 10 per cent. The arm to tongue circulation time was 18 seconds.

Four days after entry extensive bronchopneumonia developed, the patient was moribund and was treated in an oxygen tent for ten days. During his twenty-four day preoperative course congestive failure persisted, in spite of digitalis, rest and salyrgan. After diuresis he always regained edema fluid in spite of absolute bed rest. July 6, 1933, total ablation of a

6 Blumgart, H L, Berlin D D, Davis David, Rueman J E F and Weinstein A A. Treatment of Angina Pectoris and Congestive Heart Failure by Total Ablation of the Thyroid in Patients Without Thyrotoxicosis. X. With Particular Reference to the Pre and Post operative Medical Management. Ann Int Med 7 1469 (June) 1934.

normal thyroid gland was performed. On discharge, thirty-nine days after operation there were still occasional rales at the right base, the liver was still enlarged, and there was peripheral pitting edema. The basal metabolic rate was minus 21 per cent, the arm to tongue circulation time 24 seconds. Three months after operation the patient stated that he felt improved and that he experienced precordial pain only occasionally. The lungs were clear, the liver was not palpable, there was slight but definite pitting edema over the legs in spite of almost constant bed rest. Nine months after operation the patient noted that in spite of prolonged bed rest he was still markedly dyspneic when out of bed for more than two hours, and he still experienced precordial pain on moderate exertion. Physical examination showed slight pitting edema over the sacrum and legs. The basal metabolism was minus 30 per cent.

The patient has shown relatively little improvement after operation in spite of a persistent drop in metabolism and prolonged bed rest. He still shows some signs and symptoms of congestive failure. While the patient no longer gains edema fluid at complete bed rest, he is still incapacitated to such an extent that the operation cannot be considered to have made his life significantly more comfortable. Operation in such patients who in spite of all medical measures gain edema on complete bed rest is not recommended.

Congestive failure recurred temporarily in six patients after operation. These patients had experi-

TABLE 3—Causes of Recurrent Failure or Subsequent Death in Twelve Patients with Circulatory Failure

Pulmonary edema (3 weeks postoperative)	1
Cause unknown	1

enced definite improvement after operation. In one patient with auricular fibrillation, the recurrence of congestive failure was due to the omission of digitalis, in a second, to excessive work, in a third, to the recurrence of severe bronchial asthma. In three patients, there was no known cause of recurrence of failure. With appropriate treatment they have again remained free of signs and symptoms of circulatory insufficiency from four to six months after recurrent failure (table 3). Six of our patients with congestive failure have died during the last eighteen months (table 3).

RESULTS IN PATIENTS WITH ANGINA PECTORIS

Of the seventy-five patients with chronic heart disease, angina pectoris was present in thirty-two. In nineteen of these thirty-two patients, the anginal syndrome was the major disabling factor. In the remaining thirteen patients, angina pectoris was overshadowed in five patients by cardiac asthma, and in eight by congestive failure. In two of the five patients with cardiac asthma and in four of the patients with congestive heart failure, angina pectoris was experienced at least several times a week while the patient was confined to bed. In brief, of the thirty-two patients who suffered from angina pectoris, the condition was sufficiently pronounced in twenty-five so that the therapeutic effects of the operation on this syndrome could be

definitely evaluated⁷ (table 5). The etiology of angina pectoris was arteriosclerotic or hypertensive in twenty-three patients and rheumatic in two. The ages of the patients ranged from 41 to 70 years.

Of the twenty-five patients, eight patients have had no recurrence of attacks of angina in spite of activity

* Up to the time of writing 440 days after operation we have not been able to precipitate attacks of angina pectoris in this patient (A. B.) in repeated tests.

for from three to eighteen months after operation and have required no glyceryl trinitrate. The average duration of complete relief in these patients is ten months.

Of the remaining seventeen patients, five, bedridden or completely incapacitated preoperatively, have experienced only occasional attacks since operation, are capable of undertaking considerably more activity than was previously possible, and have returned to remunerative occupations or housework. The average duration of moderate relief in these five patients is ten months. The exercise tolerance of these patients has increased more than 100 per cent. Two patients, completely relieved of anginal attacks for four and nine months, recently have suffered recurrence of attacks following an automobile accident in one instance and coronary occlusion in another. Three other patients, after striking improvement, recently have had recurrences of attacks coincident with excessive rise in metabolic rate induced by thyroid. This medication has now been discontinued. One patient, a woman, aged 70, confined to bed before operation because of angina pectoris and cardiac asthma, was completely free of symptoms for

three months after operation when she suffered coronary occlusion and died. There have been no other subsequent deaths in patients with angina pectoris.

Four patients have shown no increase in their exercise tolerance and still have attacks of angina, which are as frequent but less severe than before operation. These patients have not been able to return to work.

⁷ Riseman, J. E. F. and Stern, B. A. Standardized Exercise Tolerance Test for Patients with Angina Pectoris on Exertion. *Am. J. Med. Sc.* 188: 646, 1934.

and the results do not in our opinion justify the operative procedure. In this group of four, three patients showed preoperative metabolic rates of minus 19, minus 23 and minus 24 per cent and, in view of considerations elsewhere discussed, would not now be operated on.

SELECTION OF PATIENTS

An attempt was made to select patients who showed a relatively stationary or slowly progressive clinical course. Any definite improvement could therefore be attributed to the operation. It was felt, moreover, that although these patients were severely incapacitated

TABLE 6—Total Ablation of Normal Thyroid Gland

Number of patients with heart disease*	7
Operative deaths†	6

* No deaths in the last thirty consecutive operations

† All patients had advanced congestive failure

their cardiac lesions were relatively nonprogressive, so that the benefit conferred by the operation would be maintained. Patients with short histories of rapidly progressive heart disease, on the other hand, might be expected to show only temporary improvement,⁸ since the induction of the hypothyroid state would not presumably retard the progress of the underlying pathologic condition. Patients with malignant hypertension and similarly patients with rheumatic, syphilitic or arteriosclerotic heart disease who gave a short but rapidly progressive history of congestive failure or angina pectoris have not been operated on. Our present conception of the patient with congestive failure most likely to gain the greatest benefit from operation is one with rheumatic or hypertensive arteriosclerotic heart disease who, despite a long history of frequent episodes of decompensation after moderate exertion, nevertheless becomes compensated on rest in bed. Such a patient is usually economically incapacitated but not constantly confined to bed. The basal metabolic rate should preferably be not lower than minus 10 per cent,

and the patient should show none of the unfavorable factors mentioned later.

For reasons to be discussed later, we have come to regard a preoperative basal metabolic rate lower than minus 15 per cent as an unfavorable factor and are disinclined to operate when the basal metabolic rate is lower than minus 20 per cent. The basal metabolic readings in congestive failure with no hyperthyroidism are frequently very high.⁹ For this reason, we do not consider the metabolic rate readings true basal measurements until the patient has become free from the signs of congestive failure on complete bed rest. Duplicate measurements were always made and repeated on

different days, until the averages of such duplicate analyses checked within 5 per cent.

Only patients who showed repeated attacks of angina pectoris while at rest in bed or who showed characteristic attacks after given amounts of exercise under standardized conditions are included in this report¹⁰ (table 4). The value of the standardized exercise tolerance test as an aid in diagnosis and as a means of evaluating treatment has been outlined elsewhere.⁷ The patient with angina pectoris most likely to derive the greatest benefit is one who develops attacks on slight or moderate exertion but not at rest and whose basal metabolic rate is not lower than minus 10 per cent.

Since the effect of total thyroidectomy on the immune reactions of acute infections is unknown, the operation has not been performed in the presence of clinical evidence of active rheumatic fever. It would, moreover, be difficult to judge whether improvement in such patients was due to the cessation of active infection or was the result of thyroidectomy. Patients with active pulmonary infection, such as bronchiectasis, as well as those with recent vascular accidents or marked renal insufficiency were considered unsuitable subjects. Healed coronary thrombosis is not considered a contraindication to operation. Fourteen of our patients had a history of from one to three attacks of coronary thrombosis, but in every instance the last attack had occurred at least four months before operation.

PREOPERATIVE MANAGEMENT

All our patients were poor risks in the ordinary surgical sense. Every possible aid was utilized to bring the patient to the best preoperative condition.⁶ Operation in the presence of signs of congestive failure is inadvisable. In patients with auricular fibrillation, somewhat greater doses of digitalis were employed, so that the ventricular rate would be adequately controlled during operation. All sedatives used during the operative and postoperative course were administered days or weeks before operation to be certain that idiosyncrasies or hypersensitivity were not present. In several patients who showed excitement after morphine, other sedatives were used. Oxygen therapy was used when indicated as a prophylactic and therapeutic measure.¹¹ Special nurses trained to recognize early complications cared for the patients under the supervision of the medical service.

POSTOPERATIVE MORTALITY

The operative mortality for the entire series was 8 per cent, six patients having died within the first week after operation. All deaths were due to postoperative pulmonary complications and all occurred in patients with advanced congestive failure. No patient with angina pectoris uncomplicated by congestive failure died during or shortly after operation. No death has occurred in the last thirty consecutive operations, although the later patients were fully as precarious risks as our earlier subjects (table 6).

SURGICAL HAZARDS

The greatest surgical hazards are postoperative cardiac failure and terminal bronchopneumonia, recurrent nerve injury, parathyroid insufficiency, and failure to remove the thyroid gland completely.

¹¹ Barach, A. L. The Therapeutic Use of Oxygen in Heart Disease, *Ann. Int. Med.* 5: 428 (Oct.) 1931.

1 *Postoperative Complications* — The incidence of postoperative complications has been reduced by careful preoperative and postoperative treatment and improved surgical technique.¹ All operations are now performed under local procaine hydrochloride anesthesia for we have found that local anesthesia carries less risk than general anesthesia and is attended by relatively little reaction. The incidence of postoperative pulmonary complications has been lessened by the employment of minimal sedation.

2 *Recurrent Laryngeal Nerves* — The recurrent laryngeal nerves represent the greatest surgical hazard of the operation because of their intimate anatomic relation to the thyroid and their variable position. Not infrequently the recurrent nerves may actually course through a portion of the gland substance. This problem has been fully discussed by one of us.¹² Operative speed is hazardous and unnecessary. There have been twelve unilateral nerve injuries in this series of which nine have been transient paralyses (table 7). As a reliable means of preventing bilateral laryngeal paralysis, direct laryngoscopy is performed by Dr L. M. Freedman after one lobe of the thyroid has been removed.¹³ In two instances the recurrent laryngeal nerve on the first side of the operation was injured and the operation was terminated. The vocal cord later returned to normal and the other lobe of the thyroid was subsequently removed. Injury to one vocal cord involves no serious consequences. In practically all our cases the spoken voice was unaltered when one vocal cord was paralyzed. The danger of reliance on the voice test as a substitute for direct laryngoscopy is obvious.

3 *Parathyroid Insufficiency* — This has not been a serious complication in any of our cases. No patient has shown convulsions or carpopedal spasm or any of the other serious manifestations of parathyroid tetany. Parathyroid extract has never been required. Detailed studies of the problem are available in a previous communication.¹⁴ In sixteen patients transient paresthesias or positive Chvostek's or Trousseau's signs were observed after operation. Calcium medication was effective in controlling these signs and symptoms. On cessation of calcium medication from a few days to a few weeks after its institution, no recurrence of signs or symptoms was manifest in fourteen of these patients. Only two patients continue to require calcium therapy. The transient nature of the deficiency in most of these cases suggests that temporary injury to the parathyroids or to their nerves or their lymphatic or blood supply gave rise to these mild symptoms.

4 *Failure to Remove the Thyroid Gland Completely* — The failures of previous investigators¹⁵ as well as of

ourselves¹ to achieve favorable results in the treatment of chronic heart disease by maximal subtotal thyroidectomy convinced us of the necessity of removing every vestige of thyroid. In two earlier patients minute remnants of thyroid, close to the recurrent laryngeal nerves, were not removed, the lowering in the metabolic rate was only temporary and, correspondingly, clinical improvement was present for only a few weeks.¹ In these patients, as well as in others too ill for operation, roentgen radiation used either alone or as an adjunct to maximal subtotal thyroidectomy has failed to produce any appreciable persistent lowering of the basal metabolic rate.¹⁶ For these reasons, all seventy-five patients in this series were subjected to total ablation of the thyroid gland. Without exception, evidence of persistent hypothyroidism has developed.

MECHANISM OF THE EARLY RELIEF OF SYMPTOMS

Immediately after operation many patients with angina pectoris or congestive failure have shown disappearance of localized areas of hyperesthesia and hyperalgesia and of precordial pains constantly present before operation. Patients with angina pectoris subject to frequent attacks at complete rest have noted the absence of any further attacks immediately after operation. This early relief is experienced before changes in the basal metabolic rate or velocity of blood flow occur and is due to interruption, at the time of operation, of nerve paths bearing pain impulses from the heart to the central nervous system.⁴ The early relief due to interruption of afferent nerve pathways is usually transient, with subsequent return of symptoms if the basal metabolic rate does not drop appreciably in the meantime.

MECHANISM OF THE LATE RELIEF OF SYMPTOMS AND SIGNS

The permanent relief of congestive failure and of pain of angina pectoris occurs later in the postoperative course coincident with the development of the hypothyroid state. The extent of permanent relief has generally been related to the degree of induced hypothyroidism as indicated by the reduction in the basal metabolic rate. Of six patients who showed little or no improvement, four had basal metabolic rates of approximately minus 20 per cent before operation. Because of the low preoperative level, the metabolic rate could be permitted to drop only another 10 per cent after operation before thyroid administration was required to control the distressing symptoms of myxedema. In many patients the restoration of the preoperative levels by means of thyroid caused the return of the previous signs and symptoms of congestive failure and a recurrence of attacks of angina pectoris. With discontinuation of thyroid medication, these patients soon became free from symptoms.

Extensive studies have been made of the exact mechanism whereby the hypothyroid state confers relief to patients with chronic heart disease. Earlier measurements of the velocity of blood flow in normal subjects and in various clinical conditions showed that congestive heart failure was characterized by a discrepancy between the tissue demands of the body as gaged by the metabolic rate, and the supply of blood as gaged

by the velocity of blood flow¹⁷ These considerations are graphically indicated in the accompanying chart, the black triangle representing tissue demands as gaged by the metabolic rate, and the hollow triangles, the blood supply, as indicated by the velocity of blood flow. The normal relation between the basal metabolic rate and the velocity of blood flow is represented by 1a. The relation between tissue needs and blood supply in myxedema is represented by 1b, the metabolic rate being reduced and the velocity of blood flow being correspondingly slowed. While such an individual may have a velocity of blood flow as slow as in a patient with congestive failure, the blood supply corresponds to tissue demands and the patient is therefore compensated. The situation in patients with congestive failure is shown at c in the chart, the metabolic rate being normal and the velocity of blood flow greatly slowed. There is a wide discrepancy between tissue needs and blood supply. In such a patient rest and digitalis result in clinical improvement coincident with a rise in the speed of blood flow to normal. In some patients, however, in spite of all therapeutic measures,

Relationship between the basal metabolic rate (black areas) and the velocity of blood flow (shaded areas)

the velocity of blood flow remains slow, and the patient remains decompensated. In these individuals in whom the blood supply cannot be increased, the tissue demands can be reduced by reduction of the metabolic rate after total thyroidectomy to the point at which the previously slow and inadequate circulation becomes adequate (d). The patient is thus transferred from a condition which is represented by c to one represented by b.

Our clinical experience in patients with congestive failure, together with measurements of blood flow and of the basal metabolic rate, has been in entire accord with these considerations. Previous studies have shown that there is a general parallelism between the velocity of blood flow and the minute volume output of the heart.¹⁸ Further work is in progress in regard to measurements of the minute volume output and the oxygen consumption at rest and during exercise in patients with

congestive failure. It is realized that the maintenance of velocity of blood flow represents but one factor in the expenditure of cardiac energy.¹⁹ The other factors are represented by the cardiac output, by the level of blood pressure and by the heart rate. The latter two factors have only infrequently shown any significant change either at rest or during exercise.

The same considerations underlie the benefits conferred on patients with angina pectoris. The discrepancy between tissue demands and the blood supply in such patients exists in the relation between requirements of the cardiac muscle in performing its work and the available coronary blood supply.²⁰ During exercise, the work done by the heart increases, as gaged by the increase in cardiac output and by the rise in blood pressure and heart rate. The coronary flow rises correspondingly to the limit set by its narrowed or undilatable walls. If exercise is continued beyond these limits, myocardial anoxemia develops and angina is precipitated.²¹ Our measurements indicate that after thyroidectomy the minute volume output of the heart and the velocity of blood flow is considerably reduced and so the work of the heart is greatly lessened. The body is at a lower metabolic level after thyroidectomy, and the heart performs less work at rest. Starting from a lower level of oxygen consumption the heart can withstand a greater increment of work before it reaches the level of oxygen supply set by the coronary vessels. Since the velocity of blood flow is decreased after thyroidectomy, one may assume that the coronary blood flow is also somewhat reduced in the hypothyroid state. The relative reduction in blood flow in the coronary circuit after thyroidectomy is probably not as great as the reduction in cardiac work, according to physiologic observations²² and the physical principles applying to the flow of liquids in narrowed tubes.

Our observations have shown that the hypothyroid state does not confer benefit on patients with angina pectoris by any constant changes in blood pressure or pulse rate at rest or during exercise. Similarly, more than eighty controlled observations in man have shown that the sensitivity to epinephrine administered intravenously is not altered at levels of metabolism at which clinical improvement is striking.^{22a}

SECONDARY CONSEQUENCES AND POSSIBLE UNTOWARD EFFECTS OF ARTI- FICIAL MYXEDEMA

Since removal of the thyroid does not alter the underlying cardiovascular pathologic condition, all patients must continue to receive close medical observation. The management of the cardiac condition is essentially the same as regards medication, except that the optimum metabolic level for a given patient must

be determined and the amount of thyroid required to maintain this level ascertained. Most patients have been kept at a level between minus 25 and minus 30 per cent by the administration of one-fourth grain of thyroid (Armour) daily. At this level they have been free from the disturbing symptoms of myxedema and their hearts are required to do less work than at the higher preoperative metabolic rate.²³

Since the inception of this investigation we have felt that while the development of the hypothyroid state might benefit patients with heart disease secondary untoward consequences of myxedema might offset some of the benefits of thyroidectomy. These possible secondary consequences have been studied.

The Myxedema Heart—Zondek²⁴ and Fahr²⁵ maintained that cardiac function is often impaired in patients with myxedema due to increase in heart size and diminution in voltage of the electrocardiogram. Sluggish heart action and mild congestive failure were also frequently noted by Ohler and Abramson.²⁶ Means, White and Krantz,²⁷ Christian,²⁸ Williams and Haines,²⁹ and Case,³⁰ however, studied a total of 300 patients with myxedema and concluded that heart function is rarely, if ever, impaired. In thirty-seven of our patients, changes in heart size and electrocardiographic tracings were observed and correlated with basal metabolic rate measurements.³¹ In the presence of increased cardiac size and diminished voltage of the electrocardiogram, signs and symptoms of congestive failure, instead of increasing, disappeared. That the increased cardiac size due to hypothyroidism does not subsequently cause functional impairment is shown by the persistence of clinical improvement in patients operated on from one to one and a half years before. These studies demonstrate clearly that "myxedema heart," in the sense of a causal agent precipitating circulatory failure or angina pectoris does not develop in patients with induced hypothyroidism in whom the basal metabolic rate is maintained at about minus 30 per cent.

Mental Changes—We have found that the mental torpor usually associated with spontaneous myxedema is not present in our subjects maintained at a basal metabolic level between minus 25 and minus 30 per cent. Psychologic tests performed on our patients by the psychologist conducting the investigation, Dr. Nathaniel Goldman, have shown no evidence of any unfavorable changes. Most patients state that they are able to think far more clearly than before operation, owing probably to the fact that with the subsidence of congestive failure they compare their postoperative state with the grogginess of advanced circulatory insufficiency. Although speech is somewhat slowed in some patients, mental acuity is not impaired. With meta-

bolic rates of minus 30 per cent or lower, patients not infrequently show emotional irritability and mental slowing, which are promptly alleviated by the administration of small doses of thyroid, such as one-fourth grain (0.016 Gm.) of thyroid daily.

Arteriosclerosis and Blood Cholesterol—It is believed by some observers that, in the presence of myxedema, arteriosclerotic changes advance more rapidly. The supporting evidence for this belief is by no means clear, particularly since spontaneous myxedema tends to occur in older persons who naturally show arteriosclerosis. As observed by Hurxthal³² in spontaneous myxedema, the serum cholesterol concentration has become elevated as the basal metabolic rate lowered in our patients. Clinical observations in our patients have failed to reveal any evidence of progressive arteriosclerosis up to the present.

Urinary Changes—The possibility that a decreased blood flow to the kidneys might result in impaired renal function, as indicated by albuminuria and the appearance of abnormal elements in the urine, has been investigated by Dr. H. A. Derow. Repeated studies over a period of eighteen months have failed to reveal any such changes.

Anemia—The so-called anemia of spontaneous myxedema is a well recognized entity.³³ Many of our patients have shown a decrease of from one half to one million red blood cells per cubic millimeter, with a proportionate decrease in hemoglobin concentration. After reaching these levels, there have been no further progressive changes. These changes have not resulted in any symptoms and probably represent an adjustment by the hematopoietic system to the hypothyroid state. No patient has required thyroid or iron for the treatment of anemia.

Changes in Gastric Secretion—Routine analyses of the gastric contents before and at varying intervals after operation have been performed by Dr. Benjamin Alexander in a series of patients. With the development of the hypothyroid state there has been a definite lowering in the free hydrochloric acid secretion of the stomach, but in no case has anacidity been noted.

CONCLUSION

The beneficial results that have been achieved by complete thyroidectomy in patients with congestive failure and angina pectoris warrant the further application of this procedure in patients who, in spite of all available medical procedures, are incapacitated. The precautions to be exercised in the selection of cases in the preoperative, operative and postoperative management, and in the treatment of the various complications, must be rigidly adhered to if the operative risk is to be reduced to a minimum and the fullest possible benefit is to be conferred on such patients.

330 Brookline Avenue.

ABSTRACT OF DISCUSSION

DR. SAMUEL A. LEVINE, Boston. I shall summarize the results of thyroidectomy for intractable heart disease performed at the Peter Bent Brigham Hospital. The first two cases were subtotal thyroidectomies performed in 1927 and 1932 respectively. The first total removal of the normal gland for intractable heart disease was performed on Dec. 14, 1932. Postmortem examination in this case nine months later failed

to show any remaining thyroid tissue. E. C. Cutler performed this and all subsequent operations here reported at the same hospital. Although the criteria for selection are as yet not clear, one prerequisite we have insisted on before advising this operation is that it must be certain that the patient has been treated adequately and has not improved, and that he is unable to work. There has been little to lose or to look forward to in those selected if left to the ordinary methods of treatment. In this second series I report thirty cases, twenty-three with angina, all having attacks at rest as well as on effort, and seven cases of congestive heart failure, six with mitral stenosis and one nonvalvular. There were two operative mortalities, 6.7 per cent. In the twenty-three cases of angina the results were excellent in eight, good in seven, moderate in three and fair in two. Two patients died within twenty-four hours after the operation, and another a week later of coronary thrombosis. For the seven cases with congestive failure, the results were excellent in four, good in one, moderate in one and no improvement in one. The results need to be reconsidered because the mild myxedema induced carries with it some handicaps, both for the present and for the future, of deleterious processes. Despite this, when it is appreciated that the cases so far selected had a poor prognosis as to life expectancy and comfort, the importance of possible harmful late effects loses much of its significance if increased comfort is obtained. When I first suggested to Dr. Blumgart a generous subtotal thyroidectomy in hopeless chronic cardiac cases it was because of a chance removal of a normal gland followed by an unexpected striking improvement in a patient with stubborn congestive heart failure. The explanation of the improvement when it occurs either in the anginal or in the congestive group is a difficult matter. For the present I would caution against too great optimism and urge that total thyroidectomies be undertaken with great circumspection. Notwithstanding this, I believe this operation will add to our means in the treatment of chronic intractable heart disease.

DR J. H. MEANS, Boston. It would be desirable to point out that it is fair to look on this work as the joint contribution of Drs. Blumgart and Levine. These men, since their first joint publication, have worked in separate clinics and that is perhaps well because it means that the amount of material studied has been that much greater. The early operative cases at the Beth Israel Hospital, which I saw, were very convincing and I sent one of my patients there to be operated on. He had chronic pulmonary heart disease with extreme emphysema. The result was so brilliant that I was very much impressed. At the Massachusetts General Hospital we have operated on eleven patients. The mortality has been rather high. Two patients died of postoperative causes and two died within a few months, so that our mortality is four out of eleven, which is much higher than it should be. This was due to bad selection of cases and not to incompetence of our surgeons. I think the internists are responsible for this mortality because of unwise selection of cases. Our cases have all been ones of congestive failure. One patient who had angina had an infarct and had congestive failure as well. We have not had the experience with an uncomplicated case of angina pectoris, of which the authors spoke. I think it is a perfectly logical procedure in angina. It may turn out the most favorable type of case to treat. I feel that we should look on this work with open minds and should watch the progress of these operative cases carefully. We can't say, in less than two years, what the ultimate outcome will be. It may turn out that we have merely postponed the evil day for a year or two. Perhaps in ten years very few of these operations will be done. We shall have to pursue a policy of intelligent, watchful waiting to evaluate properly what seems at the moment to be a very important therapeutic advance.

DR R. R. SNOWDEN, Pittsburgh. The material presented, especially the clinical records with the ultimate results in this series of properly selected cases, indicates that this is a bold therapeutic procedure, which is useful if properly controlled. It represents fundamentally the reduction of the demand on the heart to a level that is within the capacity of the heart. If that basic principle is borne in mind, together with other features insisted on by the authors, the procedure can be used with great effectiveness. Perhaps the results are only temporary, but even so, if a year of comfort can be added to the

patient's life, it is very much worth while. I feel that perhaps a definite warning is in order. The rather striking results attending certain cases are such that there may be an epidemic of removal of thyroid for heart disease. Care should be taken that this does not occur. Cases should be very carefully selected. Most important, I believe, is the insistence that the total amount of thyroid material be removed, because a partial thyroidectomy will give only the most transitory beneficial effects. Total thyroidectomy as a surgical procedure has its own distinct technical problems, and therefore it should not be undertaken by any surgeon unless he is familiar with the peculiar difficulties of it. I would suggest very careful selection not only of suitable cases but also of the surgeon.

DR WILLIAM B. PORTER, Richmond, Va. The authors have presented data that appear to establish unequivocally the therapeutic value of total ablation of the thyroid gland in aiding the adjustment mechanisms in chronic organic heart disease. The introduction of this procedure must be accepted as a challenge to the physician, for the safe and sane use of so drastic a measure in the symptomatic control of disease is fraught with many pitfalls. One has only to recall the long period elapsing between Withering's accurate description of the therapeutic use of digitalis and the general comprehension by the profession of its indication, proper dosage and limitations. The indications for and limitations of this new procedure have been admirably presented by Drs. Blumgart and Berlin, yet one feels some misgivings about their general application. The selection of patients for total ablation of the thyroid gland must be made from that group of patients who have not regained adequate cardiac reserve following the use of established therapeutic measures and in whom the pathologic lesions in the heart are not of a rapidly progressive nature. What constitutes adequate therapy is largely a matter of individual opinion, and one's opinion is based on one's knowledge and experience in a given field. That the majority of patients referred as suitable candidates for ablation of the thyroid gland have not been adequately treated is demonstrated by the fact that satisfactory clinical improvement has followed admission to the wards for study and treatment. The crux of the whole matter is the differentiation between progressive heart failure due to active pathologic lesions and recurring or irreducible heart failure accompanying advanced stationary lesions. It is my opinion that only in the latter group does one find those patients who may be justifiably expected to respond favorably after reduction of the oxygen requirements. It is reasonable to suggest that ablation of the thyroid gland is a therapeutic measure in cardiovascular disease remain for the present in the hands of experienced and specially trained internists and surgeons.

DR W. O. THOMPSON, Chicago. During the administration of solution of pituitary to a patient with exophthalmic goiter, the severity of the disease increased in association with an increase in basal metabolism. The patient had typical anginal attacks before the metabolism rose, and the number and severity of these attacks increased after it rose. It has been observed that when thyrotoxicosis and angina pectoris are present in the same patient, the severity of the angina is greatly reduced when the metabolism is restored to normal by thyroidectomy. It has been noted by several observers that, in patients with myxedema, angina may first appear when the metabolism is raised by the administration of desiccated thyroid. This is related to the observation of Blumgart and his associates that in their patients with angina who have had thyroidectomies the angina can be made to recur by administering thyroid. There appears to be some relationship between angina attacks and the level of thyroid function. There are just one or two other things that should be borne in mind, particularly in view of the large number of thyroidectomies that may be expected for heart disease in the future. I recall the development of certain cardiac symptoms in patients who became myxedematous after having been made better by desiccated thyroid. For example, one patient develops dull precordial pain and frequent attacks of palpitation and tachycardia whenever her metabolism drops to a level of minus 25 per cent or lower, and these signs and symptoms disappear when the metabolism is raised to normal with thyroid. Undoubtedly the heart muscle shares in the general myxedematous condition of tissues, and one of the characteristic manifestations in myxedema is generalized muscle

weakness. The level at which this muscle weakness becomes evident varies greatly. It is certainly much greater at a level of minus 40 per cent than at a level of minus 25 per cent but in some individuals may be very striking at the higher level. In observing a large number of patients who have myxedema in comparatively mild form, with basal metabolic rates of from minus 20 to minus 30 per cent, a history of muscle weakness and most of the characteristic symptoms of myxedema can be elicited by very careful examination. The difference between such patients and patients with rates of minus 40 per cent is merely in the intensity of these signs and symptoms. Thus on the one hand there is apparently definite relief of angina by thyroidectomy and on the other hand, one should bear in mind the myxedematous condition of the heart muscle. In the evolution of improvement it will be necessary to consider the condition of the patient not immediately after thyroidectomy or two or three months afterward, but a year later because it is well known that the myxedematous condition of tissues develops very slowly.

DR. GEORGE M. CURTIS, Columbus, Ohio. This contribution is impressive for two reasons: first the careful clinical investigation and thought that form its basis and second the results which this group and others have obtained. My associates and I have made six total thyroidectomies for cardiovascular disease. Our series is, in miniature, similar to those which have been reported. We have had no tetany or no recurrent nerve injury. Total thyroidectomy has been accomplished on two patients with malignant hypertension. There ensued a fall in the blood pressure both diastolic and systolic. On the other hand on rehabilitation, the elevated blood pressure returned. There was, perhaps, a fall of 20 points. Both patients are under observation. It is too early to judge of any final effects. Our best result is in the case of a woman who came to us with an elevated basal metabolic rate and an elevated blood iodine. The iodine metabolism of the six patients has been investigated. Their blood iodine was originally increased as it is in patients with hyperthyroidism. This may prove to be of significance. Subsequent to adequate management and bed rest, the blood iodine decreased. Immediately following the total thyroidectomy there ensued a marked, but transient, increase in the blood iodine. There was also a marked loss of iodine in the urine. I would add particularly to this discussion that subsequent to total thyroidectomy in man, about two thirds of the normal blood iodine disappears.

DR. EMANUEL LIBMAN, New York. At a presentation which Dr. Blumgart made in New York some eight months ago, I discussed the possibility of a nerve factor playing a role in the results. Apart from nerve sectioning I had in mind another mechanism. I have made the interesting and therapeutically valuable observation that in cases of subacromial bursitis in which, because of pain, there is difficulty in raising the arm, it often happens that the arm can be fully raised if one presses against the spine (usually at the level of the angle of the lower jaw) for from one to two minutes. Such a result may last for hours, days, weeks or even months. Because of this experience, and some clinical observations on the autonomic nervous system, I thought of the possibility of an influence on the heart, by virtue of irritation of nerves due to manipulation during the removal of the thyroid gland. Dr. Blumgart has meanwhile published studies on this question and finds that there is an early relief of pain in some cases as the result of cutting the nerves. In most cases the pain returned, to disappear again when the basal metabolism was much lowered. It would appear, therefore, that the possible factor to which I drew attention plays no role in the permanent results. As there are various causes of "angina pectoris" it is essential, particularly in therapeutic studies, to determine the cause in each case, as far as possible. The clinical picture may be due to distention or disease of the aortic wall, hypertension and coronary narrowing or closure at the orifices of the coronary arteries or in their course. It may also be due to disturbance of the cardiac nerves, spasm of the arteries and possibly edema of the heart muscle. I have drawn attention to the fact that there are cases of coronary artery disease in which the metabolism is low and the best results are not obtained until thyroid substance is administered. Dr. Thompson has just described a case of this kind. "Angina pectoris" due to coronary artery disease is to my mind part of metabolic disturbances usually called

"gouty." In these disturbances a low basal metabolism is not infrequently encountered. A study of this subject may throw further light on the results of Dr. Blumgart. It would also be of interest to study the water metabolism in the patients who have been subjected to operation. Thyroid activity may increase the discharge of water from the body. Dr. Blumgart's work represents a combination of fundamental physiologic investigations and clinical observations. The next step will be to seek a possible remedy that will eliminate the necessity of an operative procedure.

DRS. EDMUND HORGAN and JAMES ALEXANDER LYON, Washington, D. C. Total ablation of the thyroid is a formidable operation. We feel that we have accomplished similar results, without damaging effects, by doing a much simpler operation. About twelve years ago we observed, on examination of patients with recurrent exophthalmic goiter after a subtotal thyroidectomy, that there was a thrill and bruit over the thyroid arteries just as we observe it in cases of exophthalmic goiter in which operation was not performed. From this observation we got the idea that if the superior and inferior thyroid arteries were divided and ligated when a thyroidectomy was done the patient would not have a recurrence of the hyperthyroidism and it has been our practice to divide all the vessels at the superior poles and to ligate the inferior thyroid arteries in all cases of exophthalmic goiter. This practice we have carried out consistently for a number of years. Recently we made a study of a group of 300 patients from five to ten years after thyroidectomy had been performed on account of hyperthyroidism. In the group there were patients who previously had been operated on two or three times on account of persistent or recurrent hyperthyroidism. Certain patients appeared to have badly damaged hearts at the time of operation and were what is generally termed "thyrocardiacs." We were impressed by noting that the heart had returned to a condition which could be considered normal in all the cases studied except those in which organic heart disease had been present. From this observation we were led to believe that stopping the effects of hyperthyroidism in these cases was not entirely due to removal of the major portion of the thyroid gland but that the division and ligation of the superior and inferior thyroid arteries cut the pathway of nerve stimuli from the sympathetic nervous system to the thyroid and cut down the amount of blood entering the gland. This operative procedure was also shown to lower the basal metabolic rate to lessen the circulatory demands and to lighten the work of the heart. We therefore considered using the procedure of dissociation of the thyroid from the sympathetic nervous system in cases of congestive heart failure and angina pectoris. So far as we know, the procedure had not been carried out previously. We have had an opportunity to perform this operation in two cases. The beneficial results are striking. Whether the cutting of the sympathetic nerves to the thyroid gland by dividing the blood vessels cut any sympathetic fibers to the heart we are not in a position to say.

DR. HERRMANN L. BLUMGART, Boston. I am grateful to the various discussers for the many interesting points brought out, and I wish that time were sufficient to cover the numerous considerations offered for discussion. The history of ideas is always interesting, but this is hardly the time or place to present an outline of the previous work along these lines. Such summaries are available in the first communication on total thyroidectomy for chronic heart disease by Blumgart, Levine and Berlin published in the *Archives of Internal Medicine* in June 1933, and also in the paper by Blumgart, Riseman, Davis and Berlin in the same periodical in August 1933. Some points brought out by the various discussers may be grouped under several headings. One is the importance of removing the normal thyroid gland completely. Subtotal removal of the normal thyroid for nonthyrogenous heart disease was done previously by various investigators. Crile, Riesman, Boas and Shapiro, Rose, Dautrebande and others had performed such operations without obtaining sufficiently favorable results to justify subtotal thyroidectomy as a valid therapeutic measure for the relief of nonthyrogenous disabling heart disease. Dr. Levine's case of Dec. 14, 1933, to which he has just referred, likewise falls in this category. Though he states that a total thyroidectomy was done, his report of the case in the *New England Journal of Medicine* in October 1933 states that some thyroid tissue

was left about the left upper pole. This, therefore, was not a total thyroidectomy. Dr David D. Berlin had previously performed several similar maximal subtotal thyroidectomies (*Arch Int Med*, June 1933). Further discussion of the necessity for complete removal of every vestige of normal thyroid tissue is available in the several communications by Dr David D. Berlin (e.g., *Am J Surg*, July 1933) as well as in the communication by Drs Harry Friedman and H. L. Blumgart in *THE JOURNAL*, Jan 6, 1934. An interesting group of cases consists of those giving clinical evidence of thyrotoxicosis but in which the thyroid is morphologically normal. We have encountered two such cases, which do not of course form part of the group reported here. A case studied by Stricker, in which operation was performed by Leriche, and reported in 1930, likewise is in this category. Also a case observed in 1927 and first reported by Rosenblum and Levine in 1933, five months after the present investigation was begun by us, likewise showed evidences of thyrotoxicosis. The patient had a somewhat elevated metabolic rate and showed a favorable response to iodine medication. I wish that time permitted discussion of Dr Means' remarks. It was after our first failures in subtotal thyroidectomy that I consulted Dr Means and asked whether he thought it was feasible to remove the entire gland without incurring undue hazard. I feel that, were it not for his encouragement as to its practicability, we might not have attempted total ablation of the thyroid. I am in hearty accord with the opinion that the operation should not be undertaken except in a carefully selected group of patients who do not respond favorably to the usual medical procedures. I, too, have grave misgivings as to the uncritical and unskilled application of a procedure such as this, which involves surgical intervention and which in spite of our experience of no operative deaths in the last thirty-five cases must always be considered to entail an inevitable risk.

DIOXYANTHRANOL 1-8 AS A SUBSTITUTE FOR CHRYSAROBIN

HERMAN BEERMAN, M.D.

PHILADELPHIA

GEORGE V. KULCHAR, M.D.

SAN FRANCISCO

DONALD M. PILLSBURY, M.D.

AND

JOHN H. STOKES, M.D.

PHILADELPHIA

The chemical compound dioxyanthranol 1-8 differs in its structural formula from chrysarobin by the lack of the methyl group. It is formed by reduction from dioxyanthraquinone 1-8, a substance used in industry. Dioxyanthranol 1-8, under the trade name Cignolin, was introduced into dermatology in 1916 as a substitute for chrysarobin by Galewsky¹ and Unna.² The latter carried through elaborate studies of its action on normal and diseased epidermis and showed that the elimination of the methyl group was responsible for the superior activity of the drug, that the 1-8 position of the hydroxyl groups in both chrysarobin and dioxyanthranol is responsible for the antipsoriatic effect, and that the latter is approximately from two to five times

as effective as the former on the same patient. Apparently, owing to manufacturing difficulties, it was withdrawn from the market in 1924 over the protest of Grumach³ and Hauck,⁴ but in 1927, following its further use, Galewsky⁵ reported on ten years' experience with the drug, and Luth⁶ in 1927 endorsed it on seven years' experience. When in 1929 the manufacturers again decided to stop production, Kromayer⁷ came to its defense with a report of 600 cases of psoriasis in which it had been most effectively used, as well as a considerable material including other dermatoses.

Dioxyanthranol 1-8 has sustained in the literature the usual experience of a preliminary, perhaps excessive, enthusiasm, followed by some reaction but with a steady gain in fundamental support. Its use on the continent of Europe is apparently extending and it has the unpublished endorsement of several of the foremost dermatologists of Europe today. Our attention was called to it by Pautrier.⁸ It is significant that no author thus far has found the results with dioxyanthranol disappointing. Bruhns,⁹ who is the least enthusiastic about it, concedes its usefulness. Galewsky,¹⁰ Unna,¹¹ Meierowsky and Stiebel,¹² Bruck,¹³ Kretschmer,¹⁴ Ihle,¹⁵ Brinitzer and Bottstein,¹⁶ Saudeck,¹⁷ Roth,¹⁸ Schaffer,¹⁹ Werler,²⁰ Pinkus,²¹ Veiel,²² Pollard,²³ Ullmann,²⁴ Ludwig,²⁵ Grumach, Hauck, Luth, Kromayer, Nobl²⁶ and Rosenthal²⁷ were greatly impressed with the advantages of this drug in psoriasis. Unna hailed it as the greatest addition to dermatologic therapy after pyrogallol. Meierowsky and Stiebel in an experience of more than 600 cases thought it superior to chrysarobin in the infiltrated forms.

The advantages claimed for dioxyanthranol 1-8 include the following:

1. Definite chemical composition and economical synthesis from an available material.
2. Effectiveness in very low concentrations (from 0.1 to 2 per cent).

3 No constitutional symptoms such as renal irritation in these low concentrations

4 Limitation of the dermatitis-inducing action to the area of application without tendency to extension or generalization

5 No production of conjunctivitis, even when used on the face and scalp

6 Comparatively little discoloration of clothes or skin and practically no discoloration of hair in the concentrations employed

These claims for dioxyanthranol in the literature, together with favorable verbal comment from European authorities led us to give the drug a clinical trial the material for which was supplied at our request by Dr G W Raiziss. The only references to the drug in the American literature which we have been able to find are those of Ahlswede²⁶ in his textbook on dermatologic treatment, and Beckman^{26a} in his book on Treatment in General Practice. While other American dermatologists have doubtless had some experience with it, the precocious source of supply has probably interfered with its more extended study.

Dioxyanthranol 1-8 is a yellow crystalline powder, insoluble in water but easily soluble in the organic solvents and mixing readily with fat. It can replace chrysarobin in practically all combinations and may be used in ointments, lotions and paints with coal tar solution, anthrasol, salicylic acid, resorcin, sulfonated bitumen and ammoniated mercury. Petrolatum, benzene, alcohol, glycerin, chloroform and collodion may be employed in the base. Unna preferred a water-soluble varnish with gelatin. The drug is an effective addition to Dreuw's ointment^{26b} in resistant psoriasis. The color of the preparation is least noticeable in white petrolatum, and this is on the whole, an available and satisfactory ointment base.

The concentrations employed range from 0.1 to 5 per cent, but the safe effective range may be taken as from 0.1 to 1.5 per cent. It is usually advisable to test the patient's tolerance by a low concentration, such as 0.1 per cent, but most of our good results required 0.5 per cent and occasionally 1 per cent. Two per cent ointment has been known to produce an occasional severe dermatitis. That the safety range of the preparation is considerable is evidenced by an experience in the manufacture of the drug in which a chemist, handling a concentrated ether solution, accidentally splashed it on his face and arms. Although within twenty-four hours an intense dermatitis of the eyelids developed on the contact site, there was no conjunctivitis.

RESULTS OBTAINED IN FIFTY CASES OF PSORIASIS

To test the effect of dioxyanthranol 1-8 in this disease, fifty white patients with resistant psoriasis who had been subjected to various forms of treatment were treated with dioxyanthranol 1-8 in concentrations ranging from 0.1 to 1 per cent in a petrolatum base. No preparatory treatment was used, although Kromayer has particularly recommended the vigorous removal of scales to increase the effect. Forty of our patients were observed for more than one month, and twenty-four were observed from three to seven months. The process

was chronic in forty-five and in the acute phase in five patients. The duration of the psoriasis was longer than five years in twenty-five cases and in fifteen it had persisted from ten to twenty years. In nineteen cases the psoriasis was general in distribution, in twenty-nine it involved the scalp, and in six there were lesions on the face. Treatment was carried out in the winter months, when the resistance of psoriasis patients to therapeutic measures is usually at its height. The methods of treatment employed prior to the application of dioxyanthranol 1-8 included the low nitrogen diet, crude coal tar ointment and ultraviolet ray applications, ointments containing ammoniated mercury and salicylic acid, intramuscular autohemotherapy, salicin (Pernet treatment), x-rays, arsenic, chrysarobin, potassium iodide and balneotherapy. Of thirty-three patients treated by this variety of methods, seventeen had sustained a moderate improvement, three had sustained a slight improvement and only two had been cleared. Six patients were unimproved and in five cases there were no data.

In estimating the rapidity of the effect of the new drug, allowance must be made for the fact that the patients were uniformly started on 0.1 per cent, which is definitely insufficient in a number of cases, in order to test their tolerance.

EFFECT OF DIOXYANTHRANOL 1-8 ON PSORIASIS OF THE SCALP

The effect of dioxyanthranol 1-8 on psoriasis of the scalp is separately considered because of the apparently striking effect of this drug in a field in which chrysarobin cannot be used. Of the twenty-nine cases of psoriasis of the scalp, eighteen underwent complete involution, fifteen within five weeks. Seven additional cases achieved from 80 to 95 per cent involution within the same period. Four cases proved relatively resistant in that from 30 to 70 per cent involution was achieved in from one to four months. As a rule, the 0.1 per cent concentration was used and rarely the 0.25 per cent concentration.

EFFECT OF DIOXYANTHRANOL 1-8 ON PSORIASIS OF THE BODY

In treating psoriasis on the body it was rarely necessary to exceed 0.5 per cent concentration, and treatment was usually begun with 0.1 per cent. Complete involution was achieved in twenty-three cases within four months, sixteen of them within five weeks. Ninety per cent involution was achieved in seven cases within three months, five of them within four weeks. Eighty per cent involution was achieved in eight additional cases within four weeks, and seven cases achieved from 40 to 70 per cent involution in from one to four weeks. Only one case remained resistant to dioxyanthranol 1-8, and in this case the body lesions improved 50 per cent in two months but the eczematoid psoriasis of the legs was unaffected.

It should be recalled that the results described were obtained by the ambulatory-dispensary type of patients, in highly resistant psoriasis, with practically none of the attendant inconveniences of hospitalization, strenuous bathing and scrubbing, diet, slavery to the lamp, and so forth. A relapse occurred in seven patients, in two within two and one-half months after the discontinuance of the ointment. It appeared that the use of the ointment should be continued for some time after the disappearance of the last lesion in order to clinch a good result.

^{26b} Dreuw's ointment consists of salicylic acid 10 Gm., chrysarobin, 20 Gm., rectified oil of birch tar, 20 cc., green soap 25 cc., and petrolatum, 25 Gm.

TREATMENT OF OTHER DERMATOSES

While psoriasis has thus far been the principal field for dioxyanthranol 1-8, as for chrysarobin, the drug has been successfully employed in cutaneous mycoses, pityriasis rosea, seborrheic eczema, lichen simplex chronicus, lichen planus, alopecia areata, folliculitis, psoriasiform eczema, lupus verrucosus, defluvium capillitii in the young, acne indurata, parapsoriasis, intertriginous and anal eczemas (presumably mycotic), erysipeloid, edema eczematosum (Unna), ulcus cruris impetigo and herpes. In the fungous infections of the skin it has been rated as almost specific by Galewsky, Meierowsky and Stiebel, Bruck, Kretschmer, Brinitzer and Bottstein, Ihle, Saudeck, Schaffer, Bergner, Poland, Ullmann, Ludwig, Piowaty,²⁷ Grumach, Hauck, Luth, Kromayer and Kennedy.²⁸ Meierowsky and Stiebel, Brinitzer and Bottstein, Poland, Piowaty and Galewsky think that the chief domain of this drug is in the superficial mycoses. Ludwig obtained healing of mycotic eczema in from eight to fourteen days with from 0.25 to 1 per cent of dioxyanthranol 1-8. Piowaty in 1920 treated 129 cases of superficial fungous infections with 0.25 per cent dioxyanthranol 1-8 applied two or three times at intervals of from two to three days. He concluded that it was superior to iodine or hydrogen dioxide.

In pityriasis rosea Kromayer rated the effects as remarkable, stating that the 0.1 per cent ointment materially shortened the duration of the usual period of treatment. Ludwig cured his patients in from eight to fourteen days. In alopecia areata Galewsky, Piowaty and Eichholz²⁹ were especially impressed with the results. Eichholz and Piowaty rated it as the most effective drug now available in the treatment of this condition.

In sixty-five cases of sycosis, Bergner³⁰ found that he could obtain good results in the superficial variety but was not so successful in the deeper type. Polzin³¹ rapidly obtained good results in five cases of acne indurata that had resisted the usual forms of treatment. Luth over a period of three years found the drug useful in various inflammatory dermatoses.

Our own experience with the treatment of other dermatoses than psoriasis is at this writing insufficient for a full report. Our impressions of its use in alopecia areata (from 0.1 to 0.5 per cent), dermatophytosis of the hands and feet (from 0.1 to 0.5 per cent), lichen simplex chronicus and seborrheic dermatitis are very satisfactory. The involution in four cases of tinea versicolor was exceedingly rapid, although in one of these cases 0.25 per cent ointment produced a definite general dermatitis.

CONCLUSIONS

1 Dioxyanthranol 1-8, a definite synthetic chemical compound, which may be considered as chrysarobin without the methyl group, is an effective drug and a desirable substitute for chrysarobin in conditions in which chrysarobin has heretofore held the field.

2 It is usable in low concentrations (from 0.1 to 1.0 per cent), and when thus employed gives rise to

no constitutional symptoms, does not produce extensive dermatitis, produces comparatively little discoloration of the clothing, and may be used on the scalp without serious discoloration of the hair and on the face without producing conjunctivitis.

3 The European literature on this drug is extensive, in general favorable and in such extensive reports as those of Kromayer (600 cases), enthusiastic.

4 Our own experience with it indicates that it produced involution of inveterate psoriasis when a wide variety of other forms of treatment, including that with chrysarobin, had failed. This is especially true of psoriasis of the scalp. In a series of fifty patients unaffected by previous treatment over a long period of time 82 per cent had good results averaging 60 per cent involution or better, within from one week to four months, and 46 per cent were completely cleared within this period.

5 Seven relapses observed indicate that treatment should be prolonged considerably beyond the disappearance of the last lesion for the most lasting effect.

6 Mild dermatitis, mild folliculitis and slight pigmentation are occasionally produced. No albuminuria and no conjunctivitis were observed.

7 Pruritus, associated with psoriasis, was relieved in a number of cases.

8 In fungous infections of the skin the effect of the drug is second to that in psoriasis according to European authors. In alopecia areata, pityriasis rosea, sycosis barbae (superficial), seborrheic processes and a variety of other conditions very favorable results have been reported, but our own material is too small for presentation. We are favorably impressed with its action on the mycoses and alopecia areata.

9 Dioxyanthranol 1-8 is not proposed as a new drug nor one completely free from the objections familiar in the use of chrysarobin. It is none the less, we believe, a superior substitute, which deserves greater popularity now that it can be made readily available in this country.

ABSTRACT OF DISCUSSION

DR. ROBERT C. JANIFSON, Detroit. A limited experience would tend to show that the observations of the authors with regard to the therapeutic effect of dioxyanthranol 1-8 in psoriasis can be confirmed. Those who used chrysarobin twenty years ago appreciate the drawbacks of that drug, its uncertain action and its irritability. At that time a chrysarobin application could be usually depended on to produce a dermatitis with a temporary disappearance of psoriatic lesions. Old or oxidized preparations, however, were inert. After the war it was found to be almost impossible to obtain a chrysarobin that had any action whatever except for a slight staining of the normal skin. Chrysarobin had been, accordingly, almost entirely eliminated from the armamentarium, and as it had been impossible to obtain the European preparation, this new preparation, dioxyanthranol 1-8, was a welcome addition. This drug, of course, is not advocated as a cure for psoriasis, but the results obtained from its use should place it before chrysarobin or neorobin. The lessened staining properties of this preparation also commend its use, and in some cases slight change in color of the hair may be a very desirable result, especially in gray-haired individuals. I would emphasize the advisability of using the drug in very low percentages, as the authors have stated, from 0.1 to 0.25 per cent, until the action on the skin has been determined and the patient's tolerance established. Dr. Shaffer mentioned that he had one case in which a 0.25 per cent ointment produced a severe generalized

reaction. With regard to treatment of the other dermatoses that the authors have mentioned I feel that further clinical trial will be required to determine whether its efficacy will be greater or less than the medications already in use. That is particularly true with regard to alopecia areata, in which so many remedies are advised and in which almost anything will produce a cure in most cases. As is the case with chrysarobin the dermatitis produced is around the periphery rather than on the site of the lesion. In one of Dr Shaffer's cases the pigimentary reaction was so satisfactory that the ointment was applied to the entire body to produce what the patient desired, a Palm Beach tan. Continuous or intermittent use will depend on the dermal response, and I believe that caution should be employed in its use on the scalps of extreme blonds or gray-haired persons until its action has been more definitely determined. I should like to ask the authors whether they have any definite information regarding the oxidation of the drug that is, in its chemical state before it is made up in solution or ointment and if the ointment after its preparation is at all stable or will oxidize as readily as chrysarobin which was used in former years.

DR. MAX E. OBERMAYER, Chicago. When I was at the clinic in Austria we used dioxyanthranol for years for the treatment of psoriasis and more extensively in the treatment of lichenified chronic conditions such as obstinate plaques of lichen simplex or lichen planus hypertrophicus. We always found it desirable to add salicylic acid to the dioxyanthranol ointment, not only for the softening effect but also in order to prevent decomposition of the compound. Besides the clinical use however, dioxyanthranol as a chemical compound is of special interest to me because it touches on a problem on which we have been working at the University of Chicago. Our endeavor has been to isolate the active substances contained in crude coal tar which are responsible for the therapeutic effect in psoriasis. We have learned from our experiences in crude coal tar distillation that freshly distilled tar is light in color but if exposed to the air assumes at once a dark color. The extent of this darkening is directly proportional to the time of the exposure. It therefore appeared reasonable to assume that there are easily oxidized substances contained in crude coal tar. When we on the other hand examined the classes of substances successfully used in psoriasis today we were struck by the fact that most of them while chemically distinct, still present a common property, namely, they are all strongly reducing agents (chrysarobin, dioxyanthranol, anthrasol). From that it appeared reasonable to assume that the active constituents of crude coal tar belong also chemically to the same group. The presence of a reducing agent and of easily oxidized substances in crude coal tar is indicated by the change in color of the fresh distillate on exposure to the air. This led us to the idea that it might be possible to reach our object by substituting certain chemical compounds for crude coal tar and evaluating them clinically. Among the numerous substances that we used experimentally I shall mention two first because they seemed to be the more promising of the lot, secondly because their chemical structure is not unlike that of dioxyanthranol. These are catechol, or orthodihydroxybenzene and 8-hydroxyquinoline. All these compounds show one outstanding characteristic, namely that they are strongly reducing substances. We are studying at present the comparative effect of reduced and oxidized forms of the same chemical compounds on patients with psoriasis. When our studies are more complete it may well be found that the pharmacologic action of substances of the dioxyanthranol group is not much different from that of the substances active in crude coal tar.

DR. FRED D. WEIDMAN, Philadelphia. May I ask what the cost of this drug is and whether it is on the market? I should like also to state that I am grateful to have attention called anew to this, particularly in the treatment of dermatophytosis. I have used chrysarobin as third choice for a long time in selected cases. Doubtless many dermatologists will now test this new drug, and if they do and wish to get the closest and fairest comparisons with other forms of treatment they will treat different lesions on the same patient with it and with control drugs, instead of simply depending on memory as to what their past experiences have been. One group of

lesions should be treated, say, by chrysarobin, another by salicylic acid, and another by dioxyanthranol.

DR. LOUIS A. BRUNSTING, Rochester, Minn. This is interesting from the standpoint of the relationship of this drug to the coal tar products in connection with Goeckerman's work in the use of coal tar, together with ultraviolet radiation in the treatment of psoriasis. It is probable that the combination of the ultraviolet rays on the tar produces some chemical change in the tar which Julia Herrick has shown spectroscopically to be similar to that produced in ergosterol by its irradiation. Whether it is purely the oil action is not determined. The work on some of the crude coal tar products that we have been investigating similar to the work of Obermayer and that of Nelson with Osterberg in producing the tar alba has shown that the active principle is no longer contained in that preparation. I might suggest that those who have failures in connection with the use of dioxyanthranol 1-8 by its local application try also the use of the ultraviolet rays particularly through a thin film of the application. If the patient has lesions only on the elbows or on the knees we have found thatunctions of the tar over the trunk together with the ultraviolet rays to the entire body produces a more rapid involution than when treatment is limited only to the affected sites.

DR. GEORGE W. RAIZISS, Philadelphia. I had the pleasure of having prepared under my direction dioxyanthranol, the clinical application of which has been described by the authors. One may be reminded that twenty years ago the late Dr. Schamberg and I prepared a product which we called neorobin. The latter has been obtained by reducing chrysarobin with nascent hydrogen. I should like to congratulate Dr. Beerman and his collaborators on the undertaking of this interesting problem that is the development of a better treatment of psoriasis. The progress in this field has been rather slow. In this country it is only a second sustained attempt in twenty years. Chrysarobin which is essentially $C_{10}H_8O_2$ is an extract from goa powder derived from the araroba tree of Brazil. In the preparation of dioxyanthranol 1-8, which it was proposed to call anthralin almost the same method is used as in the preparation of neorobin. The difference is in the starting material which in the new preparation is dihydroxyanthraquinone 1-8. We again use nascent hydrogen for reduction. The great advantage of this product is in the fact that it is a definite chemical compound. It is easily identified by a melting point and other analytic methods. The purity of this preparation is assured because the starting material can be obtained pure. The authors stated that it is more active in psoriasis and other dermatoses than chrysarobin or neorobin. It seems to be less oxidizable than the last named products.

DR. HERMAN BEERMAN, Philadelphia. I want to preface my remarks by stating that we have not brought a new treatment for psoriasis, rather we have revived the dead. With reference to Dr. Jamieson's remarks as to the chemical properties of this compound I was hoping that Dr. Raiziss would go more into detail. However, they were amply discussed by Unna in 1916. As far as the stability is concerned, we have had the drug stored in the clinic for some three or four months in collapsible tubes and have found no particular difference in effect from the older than we have from the newer batches that we received. I am grateful to Dr. Obermayer for his remarks on the chemical functions of these compounds. As far as salicylic acid is concerned, we have refrained from the use of any other compounds in conjunction with this drug mainly to see whether or not the drug itself has any real advantages. With reference to Dr. Weidman's remarks I might state that in his original work Unna used this technic. One side of the body was painted or treated with chrysarobin of a given strength and the other side with cignolin, as it was then called. He found that in some cases the percentages of chrysarobin required were ten times as strong as of cignolin to get the same effect on lesions on the same patient at the same time. As to Dr. Brunsting's remarks about the combined use of ultraviolet rays and this compound, I can say that in alopecia areata we were obliged in some instances to resort to ultraviolet rays following the technic of Goeckerman in psoriasis, with crude coal tar. The results in a few cases treated with the ultraviolet ray combination seemed better.

DISABILITIES OF HAND RESULTING FROM LOSS OF JOINT FUNCTION

SUMNER L. KOCH, M.D.
CHICAGO

In suggesting the subject of disabilities of the hand resulting from loss of joint function I wish to submit a problem for consideration and discussion rather than a report of facts ascertained and results accomplished. To attempt to secure improvement of function in a hand with its joints fixed in flexion or extension has been difficult and often unsuccessful. An important complicating factor in many cases has been injury and fixation of tendons as a result of the original injury or infection. Not uncommonly the inability on the part of the patient to perform active movements and the failure to maintain passive movements have been quite as important factors in contributing to the joint fixation as have the injury or infection. Once joint function has been lost, the problem of restoration has presented so many difficulties that one constantly recurs in his mind to what might have been, and the problem of prevention of joint disability assumes ever increasing importance.

The rapidity with which stiffness can develop at the joints of an immobilized hand is often one of the first lessons that the surgeon learns in the treatment of hand injuries. Too often when a surgeon has immobilized one or several fingers in extension because of a metacarpal or phalangeal fracture he finds to his dismay at the end of twelve or fifteen days that the affected fingers are stiff in extension and that if he attempts gently to flex them they spring back into extension almost like a strip of spring steel. In the same way, if the fingers are kept immobilized for days or weeks in a warm wet dressing with the fingers lying extended, the thumb extended and alongside the hand, the hand and forearm in complete pronation and in slight volar flexion at the wrist joint, the resulting disability, owing in a considerable part to fixation at the joints, is exceedingly difficult to overcome. An almost equally serious disability results if the fingers are allowed to remain indefinitely in the acutely flexed position.

Once joint fixation has taken place, some form of active treatment must be undertaken in order to permit movement. Four methods are available: (1) splinting and physical therapy, (2) manipulation, (3) extra-articular operations, and (4) intra-articular operations.

SPLINTING AND PHYSICAL THERAPY

If immobilization has not been maintained for too long a time and there is not absolute fixation at the joints in question, considerable improvement can often be accomplished by splinting and judiciously applied physical therapy. Many types of splints have been devised to bring fingers fixed in extension into the position of flexion and to draw sharply flexed fingers into extension. In the application of such splints in my own work I have emphasized several principles: the use of elastic tension maintained for long periods, i. e., six, eight or ten hours of the twenty-four, relaxation of tension when it begins to cause pain, and utilization of splints that can be easily applied to the hand and easily removed.

Even a slight degree of tension may very quickly become intensely painful, and unless the tension can be regulated with exactness, and I know of no way of accomplishing this except by the use of elastic tension, either the patient will release the tension completely and so fail to secure improvement or, unless he is unusually stoical and determined to secure improved function at any cost, he will refuse to continue with the treatment. If, particularly at the beginning of the treatment, the splint can be completely removed without a great deal of effort, and so permit the patient to use contrast baths and applications of heat and to employ active and passive movement alternately with the application of tension, better cooperation will be obtained and better results secured.

MANIPULATION

The indications for manipulation of stiffened joints under anesthesia have been very accurately described by Jones and Lovett.¹ From my own observation, the attempt to secure movement in stiff joints by manipulation under an anesthetic has resulted too often in increased stiffness rather than in increased mobility. During the manipulation firm fibrous tissue has been torn, hemorrhage and swelling have resulted and attempts to preserve the degree of movement possible under the anesthetic have caused the patient such intense pain that he has insisted on absolute immobilization for the time being. When the swelling and pain have diminished and movement has again become possible, the surgeon has often found that little or nothing has been accomplished and not infrequently that the affected joints have become more firmly fixed than ever.

The occasional cases in which I have found manipulation of value have been those in which, as a result of injury or infection, intra-articular or periarticular adhesions have formed, which have not completely prevented movement but have caused persistent pain by tension on adventitious bands, newly formed connective tissue or even newly formed bone at or near the joint margin. If in such cases the part is moved at the affected joint once or twice through its complete range of motion, one can usually feel and often hear the soft crepitus as the adhesions give way. If the hand and forearm are then immobilized for twenty-four hours, and if active and passive movement is begun promptly afterward, definite improvement in function can be obtained.

I have rarely seen helpful results follow forcible manipulation at the metacarpophalangeal or interphalangeal joints, although Shaw² has stated that, in his opinion, in favorable cases the shortened collateral ligaments of the metacarpophalangeal joints can be freed from their attachment to the head of the metacarpal bone by manipulation and without open operation.

EXTRA-ARTICULAR OPERATIONS

In the small joints of the hand to a much greater extent than in joints surrounded by muscles and tendons, such as the hip and shoulder joints, stability depends on the integrity of the joint capsule, and normal mobility on the flexibility that is associated with persistent use and movement.

Fixation at these joints is seen most commonly in one of two forms—fixation in extension at the metacarpophalangeal joints, and fixation in flexion at the proximal interphalangeal joints. Fixation in extension

From the Department of Surgery, Northwestern University Medical School.
Read before the Section on Orthopedic Surgery at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

¹ Jones, Robert and Lovett, R. W. *Orthopedic Surgery*, ed. 2, New York: William Wood & Co. 1929, chapter 5.
² Shaw. Personal communication to Dr. A. B. Kanavel.

at the interphalangeal joints is fairly common, fixation in flexion at the metacarpophalangeal joints is almost never seen.

Anatomists have carefully described the small joints of the hand and have emphasized the laxness of the proximal attachment of the volar cartilaginous plate which forms the volar portion of the joint capsule of the metacarpophalangeal and interphalangeal joints, the importance of the firm collateral ligaments (fig 1), and the tenuous character of the dorsal portion of the joint capsule, as well as the part played by the extensor tendons in compensating for the lack of a well developed dorsal portion.

With reference to the metacarpophalangeal joints, Professor Blair³ says

The capsular ligament is strengthened on each side by a collateral ligament which radiates fanwise from the tubercle and adjacent depression on the side of the metacarpal head to the side of the base of the proximal phalanx and to the front of the joint capsule.

When the fingers are flexed sideward movements become impossible because of increased tension of the collateral ligaments, which are fixed to the metacarpals nearer the dorsal than the palmar surface of their heads, and are also more stretched in flexion, owing to the greater width of the palmar aspect of the metacarpal articular surface. The metacarpophalangeal joint of the thumb has much less extensive movement than the others—hardly any at all from side to side.

The interphalangeal joints are constructed, as regards to ligaments, in exactly the same fashion as the metacarpophalangeal joints.

The latter statement, however, should be qualified to include the observation that the collateral ligaments at the interphalangeal joints cannot usually be identified so readily as distinct portions of the periarticular framework but blend more definitely with the joint capsule to form an integral part of it.

It is probable that surgeons in their efforts to secure freedom of movement of fingers and hand have not paid sufficient attention to the formation of the joint capsule, to the thick and unyielding character of its volar portion, to the strength and direction of the collateral ligaments, and to the fact that in the movements of flexion and extension at the metacarpophalangeal joints and to a somewhat lesser degree at the interphalangeal joints the base of the distal bone glides forward and backward on the head of the proximal bone. Flexion at the joint, as Blair has stated, renders the collateral ligaments taut, in extension they are relaxed.

Shaw⁴ in 1920 emphasized the fact that if the fingers are kept immobilized in extension, shortening of the collateral ligaments of the metacarpophalangeal and interphalangeal joints occurs and that the shortening of these ligaments constitutes an important factor in the stiffness of the extended fingers and their resistance to movements of flexion. He showed, furthermore, that if the ligaments are carefully detached from their origin on the head of the metacarpal bone a definite degree of restoration of flexion can be obtained, and retained with the help of splinting and physical therapy.

Although various methods of splinting have been devised to mobilize the small joints of the hand with the fingers held stiff in extension, and particularly the metacarpophalangeal joints, no one else, so far as I know, had previously suggested the procedure described

by Shaw.⁴ Doubts have been expressed as to its value, but in a number of cases in which I have performed this operation excellent results have been obtained.

Following Shaw's suggestions I have approached the joint through two vertical incisions approximately 1 inch in length, made one on each side of the joint in question, and with the center of the incision over the prominent tubercle on the dorsolateral aspect of the head of the metacarpal bone. The lateral and oblique fibers of the dorsal aponeurosis, which help to unite adjacent extensor tendons, are divided, and the articular tissue at the side of the joint, underneath the dorsal aponeurosis, pushed to one side so as to expose the proximal attachment of the ligament to the tubercle and to the bone just proximal to and volarward from the tubercle (fig 2). The proximal attachment of the ligament is divided with a small sharp knife, frequently some of the periosteum is cut away as the attachment is divided. Division of a ligament on only one side of the joint has little effect as far as improvement of

Fig 1—The collateral ligaments of the joints of the fingers

flexion is concerned. As the second ligament is divided, however, definite relaxation takes place, and the proximal phalanx can then be flexed on the metacarpal bone, usually to an angle of 110 degrees or even 100 degrees, i.e., almost to a right angle.

After closure of the incisions with fine interrupted sutures, a light plaster or aluminum splint is applied to hold the fingers in flexion at the metacarpophalangeal

5 A 'transverse posterior capsulorrhaphy' was suggested in 1919 by Wilson and Heyman (Reconstructive Surgery of the Hand J A M A 73 1811 1817 [Dec 13] 1919) to overcome stiffness in extension at the metacarpophalangeal joints. The fibrous capsule of the metacarpophalangeal joint is incised transversely allowing the maximum of palmar flexion at this joint immediately.

In 1924 Heyman (The Mobilization of Stiff Metacarpophalangeal Joints Surg Gynec & Obst 39 506-507 [Oct.] 1924) again referred to this procedure. The extensor tendon is retracted to one side and the joint capsule is exposed. Attempted manipulation at this stage of the operation will demonstrate that the resistance is felt to be in the capsule of the joint. A sharp tenotome is then used to incise the capsule transversely approximately one half its circumference near its proximal attachment. Care must be taken not to injure the articulating cartilage. The proximal phalanx is then forcibly flexed to 90 degrees causing a gaping wound to appear in the capsule. The joint can then be put through its normal range of motion with little or no resistance.

Although it is probable that in such an operation the collateral ligaments would be divided or ruptured it seems obvious that such an operation is a different procedure from that described by Shaw in that it does not purposefully attack the essential structures involved and in that the joint is unnecessarily opened and exposed.

³ Blair, in Cunningham D J Textbook of Anatomy ed 6 New York: William Wood & Co 1931 pp 344-345

⁴ Shaw C G Ankylosis of the Metacarpophalangeal Joints M J Australia 2: 549 551 (Dec 18) 1920

joints. The splint is left in place for eight or nine days, until the sutures can be removed, active movement and physical therapy are then begun.

I have used this procedure in eighteen cases, one of them with involvement of the metacarpophalangeal joints of the four fingers of each hand. In four cases one metacarpophalangeal joint only was involved, in two cases two joints, in two cases three joints, in ten the metacarpophalangeal joints of all four fingers of one hand. In two of these cases the proximal interphalangeal joints of one finger and in two others the proximal interphalangeal joints of two fingers were involved as well. I have not had occasion to use it in connection with the metacarpophalangeal joint of the thumb. In no case did the patient fail to secure a definite degree of improvement (fig. 3).

Fig. 2.—Dissection to show the position of the collateral ligaments of the metacarpophalangeal joints and their relation to the joint space.

A second and common type of fixation of the fingers, not infrequently associated with fixation in extension at the metacarpophalangeal joints, is that in which the fingers are fixed in flexion at the interphalangeal joints, and particularly at the proximal interphalangeal joints.⁶ In this type of fixation there are usually complicating factors that make treatment peculiarly difficult. There may first have been an extensive loss of skin and superficial tissue on the volar surface of the hand and fingers, so that a flexion contracture of the superficial tissues has become an important factor in the disability. Secondly, as suggested in the opening paragraph, the flexor tendons may have been injured and become fixed by scar tissue with the result that the fingers are held as in a vise and any efforts to extend them passively are met by an absolutely rigid resistance. Finally the contraction of the joint capsule and the accessory liga-

ments, the result of the original injury or infection, of prolonged fixation in flexion, or of a combination of these factors, plays an important part in the disability. Although one cannot ignore the part played by contraction of the superficial tissues and by tendon fixation, I wish at this time to consider only the rôle of the joint capsule. Perhaps it is sufficient for the moment to say that frequently some method of replacing lost skin and subcutaneous tissue must be combined with the operation on the joints and that often fibrosed and contracted tendons must be freed and lengthened, or must be freed and divided with the idea of inserting a graft at a second operation after the joints have been successfully mobilized.

To Silver⁷ particularly belongs the credit for emphasizing the important rôle that contraction of the joint capsule plays in this type of contracture and for describing an effective method of treatment—subperiosteal separation of the joint capsule, usually on the side of the convex or condylar segment of the joint.

As compared with forcible correction it affords a means of overcoming contractures not amenable to force, of avoiding the danger of fracture as well as of troublesome reaction from traumatism, and of causing less pain. Over simple capsulotomy it offers the advantage of preserving the continuity of the capsule with the consequent shorter period of fixation and the lesser danger of recontracture. It also has the very decided advantage that in most joints it can be performed subcutaneously, thus making of it a decidedly simple procedure.

The skin is first incised with an ordinary tenotome, well on the side of the joint and close to the joint line, the blade is carried down to the bone and then the capsule alone is split longitudinally from the joint line to its insertion. The elevator is now introduced and the attachment of the capsule is separated.

It must not be expected that the contracture can be fully corrected in all cases after the capsule has been freed. This will depend on how much the other tissues are implicated. When the capsule is the chief factor, however, the moderate resistance in the other tissues can be expected to yield to the gradual method of correction before the periosteum has a chance to readhere.

I have had the opportunity of carrying out Silver's procedure in a few cases, five, to be exact, and believe that when the volar capsule is chiefly at fault such an operation is definitely superior to violent rupture of the capsule by blunt force. I have, however, been impressed with the fact that not infrequently shortening of the collateral ligaments as well as shortening of the volar portion of the joint capsule plays an important part in the fixation in flexion at the proximal interphalangeal joints, just as it does in fixation in extension at the metacarpophalangeal and interphalangeal joints. In such cases unless the shortened collateral ligaments are divided or freed from their proximal attachment relaxation will not be obtained and recurrence of the flexion deformity will take place.

This apparently paradoxical statement will be made clear if one remembers that, at the proximal interphalangeal joints, flexion to an angle of less than 90 degrees can take place under normal conditions. The collateral ligaments (fig. 1), which become taut during the movement of flexion, again relax as the middle phalanx passes through the arc of 90 degrees to form an angle of less than 90 degrees with the proximal phalanx. With prolonged fixation in a position of acute

6 It will be remembered that the proximal interphalangeal joint is the only one of the three finger joints at which flexion to an angle less than 90 degrees is possible under normal conditions.

7 Silver, D. The Role of the Capsule in Joint Contractures with Especial Reference to Subperiosteal Separation. *J. Bone & Joint Surg.* 9: 96-103 (Jan.) 1927.

flexion the immobile ligaments, particularly if involved in an inflammatory process, undergo contraction and finally play a definite part in the flexion contracture just as does the contracted volar portion of the joint capsule. In such cases, to secure permanent relaxation, one must divide the proximal attachment of the collateral ligaments as well as the proximal attachment of the volar capsule.

INTRA-ARTICULAR OPERATIONS

Intra-articular operations to make possible movement at the joints at which ankylosis has taken place as a result of infection or injury have long been well recognized surgical procedures but the attention of surgeons has been focused on the large joints—the hip, the knee and the elbow joints in particular, rather than on the joints of the hand and wrist. There are a number of obvious reasons for this fact. Joints that are surrounded by powerful muscles and tendons derive a definite stability from these supporting structures, and the capsule of such joints can be incised or partially divided with a certain degree of impunity as far as the stability of the joint is concerned. In the fingers, on the contrary, there are practically but two tendons that pass the joints—the flexor tendons on the volar surface and the extensor on the dorsal surface. In these joints, therefore, stability depends largely on an intact joint capsule, and, because of the unavoidable injury of the capsule whenever the joint is adequately exposed or removal of one or both of its articular surfaces becomes necessary, any intra-articular operation is associated with the definite risk of formation of a flail joint or of persistent subluxation.

Moreover, as has already been emphasized, in the fingers the tendons are frequently fixed and often hopelessly injured as a result of the injury or infection that resulted in joint fixation. In such cases any operative attack on the joints must be followed by tenolysis or tendon grafting so as to restore active movement after free passive movement has been made possible. The combined difficulties of these necessary surgical procedures may preclude their employment or make it impracticable to carry them out.

A third reason for the reluctance of surgeons to attempt intra-articular procedures on the small joints

of the hand is the almost complete absence of soft tissue in the neighborhood of joints from which to fashion a flap to turn into a newly formed joint cavity. Whether such a procedure is essential or not if one is to secure a movable joint,⁸ the dicta of Murphy⁹ have impressed themselves so strongly on the surgical profession that, according to MacAusland,¹⁰ "the methods (of performing arthroplasty) in use today have in common the exposing of the joint surfaces, modeling of the bone-ends after the conformation of the normal joint and the interposition of a substance to obstruct effectively bony union."

Still another and probably the most important reason for the concentration of attention on joints other than those of the hand and wrist is the fact that even with complete ankylosis at the wrist or at some of the small joints of the hand a considerable degree of function of the hand is often retained, and the patient adjusts himself so well to the handicap present that any operative procedure to secure improved function seems to him unnecessary or ill advised.

In attempting to secure movement at the wrist joint in cases in which bony fusion has taken place, I have paid particular attention to several details that have seemed to me of importance. These are (1) exposure of the joint by two lateral incisions, one on the radial and one on the ulnar side, so as to give adequate access to the entire joint area with a minimum of traction on and trauma of extensor tendons, (2) removal of sufficient bone to ensure an adequate joint space, which at times means removal of both rows of carpal bones, (3) shaping the contour of the newly formed joint surfaces so that they resemble as nearly as possible those of the normal joint, and (4) the securing of smooth bone margins so as to avoid leaving overhanging edges of

Fig 4—Result of arthroplasty for bony ankylosis at the wrist joint. *A* before operation *B* *C* and *D* after operation

bone which might predispose to new formation of bone and subsequent interference with freedom of movement.

⁸ It matters little in experiments on the normal knee and elbow joints of dogs whether arthroplasty is performed by the no-flap pedunculated flap or free flap method. The flaps when used very largely break down and the newly formed joint is about the same both structurally and functionally following the three types of operations (Phemister D B and Miller E M The Method of New Joint Formation in Arthroplasty Surg. Gynec. & Obst. 26 445 [April 1918])

⁹ Murphy J B Arthroplasty Ann Surg 57 593-647 1913

¹⁰ MacAusland W R Mobilization of Ankylosed Joints Surg, Gynec. & Obst. 37 255 309 (Sept.) 1923

Instead of covering the exposed end of the freshened radius with a covering of fascia, as described and pictured by MacAusland, I have in some cases interposed free flaps of fat between the newly formed joint surfaces, in other cases no tissue whatever has been interposed. In operations on the smaller joints, both pedunculated flaps of fascia and free transplants of fat have been used, in a few cases no soft tissue has been interposed between the freshened bone surfaces.

My cases of intra-articular operations include eleven arthroplasties at the wrist joint in eleven patients (fig 4), two arthroplasties at the metacarpocarpal joint in two patients, eighteen arthroplasties at the metacarpophalangeal joints in eleven patients, twelve arthroplasties at the proximal interphalangeal joints in eight patients (fig 5), and five arthroplasties at the distal interphalangeal joints in five patients.

I should like to be able to say that the results in the entire series have been good, but unfortunately such has not been the case. Of eleven patients on whom arthroplasty at the wrist joint was performed, a bony

at the small joints of the hand if movement is begun promptly after operation, if the patient is intelligent and cooperative, and if postoperative physical therapy, efficiently applied, is combined with and promptly followed by active use of the hand.

SUMMARY

Disabilities of the hand due to loss of joint function are so common and so difficult of correction, once they have developed, that one cannot lay too great stress on their prevention following infection and injury by maintaining the immobilized hand in the position of function and by inaugurating active movement at the affected joints at the earliest possible moment.

If the disability, once it has developed, is confined to a limitation of movement, improvement can frequently be obtained by the efficient use of splints and the application of well directed physical therapy.

Manipulation under an anesthetic is helpful in a few and in well selected cases but, as often carried out, is quite as likely to increase the disability as to lessen it.

Fig 5—Result of arthroplasty at the proximal interphalangeal joints for bony ankylosis following a saw cut injury of the middle and ring fingers. A and B before operation, C, D and E, result five months after operation.

ankylosis again developed in two, although in a position more favorable for function, one after six years had "slight movement", one after four years "fair movement", four obtained results that can be considered excellent. One patient has been operated on so recently that no statement concerning a result can be made at this time, two patients have dropped out of sight.

The results of thirty-seven arthroplasties at the small joints of the hand in twenty-one different patients have been very similar. In six patients there was a recurrence of the ankylosis, or the range of movement was so slight that the degree of improvement was negligible, in one patient in whom after a severe mangle burn bony ankylosis developed at practically all the small joints of the four fingers, and on whom arthroplasty was carried out at the four metacarpophalangeal joints, the proximal interphalangeal joints of the index, middle and ring fingers and the distal interphalangeal joint of the index, instability resulted, with so great a tendency to the formation of flail joints that a retentive apparatus became necessary, in three patients there was a fair degree of improvement, in eight patients the result could be considered satisfactory. Three patients have dropped out of sight and the late result is unknown.

In spite of these rather discouraging results I feel that much can be accomplished in cases of bony ankylosis by a well performed arthroplasty at the wrist and

If complete fixation has taken place, some form of active surgical treatment must be carried out. Shaw's operation, separation of the collateral ligaments from their proximal attachment, has proved of definite value in cases of fixation in extension at the metacarpophalangeal and interphalangeal joints. Silver's operation, subperiosteal separation of the volar portion of the joint capsule from its proximal attachment, has been of value in selected cases of fixation in flexion at the interphalangeal joints.

If bony ankylosis has developed, arthroplasty comes into consideration. Although the results in my experience have been far from perfect, definite improvement has been secured in a considerable group of cases and I believe that, with greater care in the operative procedure and more persistent efforts to secure active movement following operation, still better results can be attained.

54 East Erie Street

ABSTRACT OF DISCUSSION

DR. WALTER G. STERN, Cleveland: I agree that the mobility of the wrist and fingers must be preserved but I do not feel that the necessary procedures and the ability to preserve motion finally are as easy as the speaker would have us believe. There are many causes for loss of joint motion besides direct trauma and the swellings therefrom or direct inflammatory processes. I have long divided people into "swellers" and "nonswellers"

or if you will into those who are liable to traumatic trophedema and those who are not and I have often found that even trivial injuries to the hand give rise to swelling and stiffness in any or all the joints of the upper extremity. This condition has been well described by German authors as "metatraumatische vasomotorische trophoneurose" and these authors give warning that even seemingly trivial injuries to the phalanges in susceptible individuals may result in trophedema and ankylosis even of the shoulder joint. It is well to bear this condition in mind in disputed medicolegal cases. The most important function to restore especially in working men is the flexion of the fingers and the apposition of the thumb to the grasping function of the hand. Extension of the fingers can often well take care of itself because there is always a certain amount of elastic rebound when the fingers are flexed; if these patients can be given enough active flexion motion to grasp their tools occupational therapy can be begun. After directing three large and well equipped physical therapy departments in three different hospitals I am skeptical of the amount of good that is accomplished by the ordinary routine physical therapy treatments and I am not a great believer in the efficacy of physical therapy unless it is applied as it was applied to the soldiers who were placed in development battalions of the army in the late war. Physical therapy to do any good must be kept up in some form or other for hours a day. I do not believe that by a paraffin bath followed by fifteen minutes of rubbing one can accomplish much in restoring the flexibility of the fingers. That is why I believe such an elastic apparatus as has been shown here is the proper way to proceed. Occupational therapy too must be constantly carried out and the patient must work as many hours a day in flexing and mobilizing his fingers as he would if actually engaged in earning his livelihood.

DR. ARTHUR STEINBLER, Iowa City. I am heartily in accord with the author that the problem is one of early and gradual mobilization. The principle of the splints can be classified as rigid, semirigid and elastic. I am an adherent of the elastic traction and I use the methods of which these are some examples because my experience with this situation has shown me to what degree elastic traction is capable of overcoming contractures by gradually accomplishing adaptation of the tissues. Manipulation is likewise a suitable method. I don't believe in the treatment of joints except under certain circumstances. There comes a time when the purely conservative methods fail because of the irresistible resistance of the capsular structures. The method of Dr. Silver is an excellent one. I have used capsular strippings in a good many cases for the contraction of the fingers not always inflammatory, many of them being rigid. After a time it becomes quite obvious that the contracture has passed the degree at which any amount of lengthening of the lateral ligament will enable one to straighten out the finger. Then it is a question of adapting the skeleton to the shortened tendon. In many cases of arthritic contractions I have found it necessary to resort to the resection of the metacarpal heads—a procedure that is quite gratifying when one considers the original condition. The same applies to a great number of resistant cases of ischemic contracture in which the deep flexor of the thumb must be lengthened without sacrificing the principle of conservatism that acts as a guide in these cases. I have had about sixty cases of ischemic contractures and had to resort to the plastic lengthenings in some instances. One word in regard to arthroplasty. As to the wrist I have had no experience with it. I have performed in all about ninety-three arthroplasties with generally satisfactory results but I am willing to except the arthroplasty of the wrist. Arthroplasty of the fingers has not given uniform results.

DR. L. E. PAPURT, Cleveland. The thing that has always impressed me is the gentleness with which one must touch the hand. When one remembers the multitude of nerves and tendons and joints that are included in a small organ like the hand it can be seen how much damage can be done by even small swellings. I want to ask Dr. Koch regarding the baseball finger with a small fracture or without a fracture. In spite of what is done these patients will get stiff joints. Recently I had a series of three patients, one, a dentist with an injured index finger, another, a violinist with an injured

small finger and a third, a banker, with an injured index finger. The particular joint affected of all three patients was extremely important for use in their professions. It was my opinion that these swellings were due to the intra articular effusion and hemorrhage causing pressure on the capsule with hyperplasia of the cells of the capsule and extreme thickening. That is seen when capsulotomies or strippings are done. Sometimes a capsule will be four or five times the normal thickness. It was my idea to make a small incision through the capsule of that joint immediately and allow the hemorrhage and effusion to come out. I have done that only once and the patient got along very well. I should like to ask whether Dr. Koch thinks this is a rational way of treating it. I should also like to show this ordinary glove for elastic extension. It is not complicated and may not be used for some of the more severe cases but I get a well fitting glove, apply hooks and put a stiff splint in the back. Splints can be made to put in pieces of whalebone running up to that joint. I have used this successfully for elastic extension. The patient should be instructed to buy a good leather glove that fits his hand snugly.

DR. SUMNER L. S. KOCH, Chicago. I am not sure what Dr. Papurt means by baseball finger. I think of a baseball finger as one suddenly and forcibly flexed at the distal interphalangeal joint with rupture of the extensor tendon.

DR. PAPURT. I didn't mean that. One has these fingers when they get an injury on the end occasionally a small fracture.

DR. KOCH. I have had occasion to operate in one or two such cases. I found that the inability to flex the finger was due to fibrosis about the flexor tendon resulting from the hemorrhage that had taken place at the time of the injury. I do not know, if one saw such a case immediately after the injury whether it would be wise to open the joint and remove the extravasated fluid. I would prefer to immobilize the finger for a brief period and then try to secure active movement as early as possible.

FRACTURE OF BOTH BONES OF THE LEG

TREATED BY A MODIFIED BOEHLER METHOD
WITH A NEW APPARATUS

R. A. GRISWOLD, M.D.

LOUISVILLE, KY.

Major fractures of the tibia and fibula represent an increasingly important part of the work of the orthopedic surgeon. The majority of such cases seen today follow traffic accidents. The "bumper" fracture of the knee, so common a few years ago, has been replaced by a fracture of both bones below the knee, as the result of changes in automobile design. These fractures are usually badly comminuted and displaced and there is severe damage to the soft tissues. They are often compounded by direct force, and dirt is driven deeply into the wound.

The usual methods of treatment having been shown inadequate to deal with the large number of such cases admitted to the Louisville City Hospital in the last few years, it seemed desirable sometime ago to adopt newer procedures. The objectives sought were (1) accurate anatomic reduction and firm fixation to insure the best anatomic and functional result, (2) adequate treatment of compound wounds without sacrifice of or interference with position and (3) ambulatory treatment to decrease hospitalization and to allow the patient to return to his normal activities as soon as possible as

From the Department of Surgery of the Louisville City Hospital and the University of Louisville School of Medicine.
Read before the Section on Orthopedic Surgery at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

well as to aid healing by the natural physical therapy of active use. These objectives were obtained by applying skeletal control to both fragments, a procedure used in various forms by Caldwell,¹ West,² Eikenbary and Lecocq,³ Anderson⁴ and others.⁵ Steel pins have been

Fig 1—The apparatus, showing A the vertical caliper which holds the proximal pin or wire. The worm gear, B, closes this caliper to grasp the pin or opens it to tighten the wire. The distal caliper is similarly constructed. The knob, C, controls the worm and rack that supplies lateral angulation to the distal fragments. Traction is obtained through screw D. Rotation is possible at E and F. Flexion or extension of the knee is possible by lowering or raising the jack G. The base telescopes to fit the length of the extremity.

used in preference to wires, since the inherent rigidity of the pin makes it superior for fixation in plaster with the added strain of weight bearing. An apparatus was designed to manipulate these pins and to maintain position during the period of treatment of the soft tissue injuries and the application of plaster. The pins have been firmly incorporated in nonpadded plaster casts to permit immediate ambulatory treatment without danger of displacement of the fragments.

The essentials of the apparatus are (1) a device to hold the upper pin and to align the proximal fragments

Fig 2—Patient in the apparatus with fracture reduced and checked by roentgenogram. The pin point compound wound is covered with a light dressing. Cast applied seventy-two hours after fracture.

in the apparatus, and (2) a "mechanical hand" to grasp the distal pin and to apply traction, rotation and angu-

lation to the distal fragment. The first rather crude apparatus⁶ satisfied these requirements fairly well but was cumbersome in adjustment, difficult to drape for debridement, and interfered with roentgenologic control. The present apparatus is the result of considerable experience in the use of the method and has eliminated the foregoing disadvantages. It permits the reduction of fractures of the leg with precision comparable to that exhibited by other mechanical arts and is adaptable to use with either pins or wires (fig 1).

At the proximal end is mounted a vertical caliper (A), which may be closed by a worm gear (B) at the base to grasp the pin or may be opened to tighten a wire. The entire caliper pivots to align the proximal fragment and may be locked in position. The distal caliper is similarly constructed but is placed horizontally. Both calipers are designed to give the maximum amount of room about the extremity for operations, dressings and the application of plaster. Lateral angulation of the distal fragment is provided by a worm and gear rack (C). This rack is the arc of a circle drawn from the center of the pin and permits angulation without lateral motion. This caliper is offset $1\frac{1}{2}$ inches (the average distance from the midline of the tibia to the middle of the body of the os calcis) below the traction screw (D). Rotation is permitted in the axis (E) of the caliper or the axis (F) of the screw, insuring rotation in the line of the tibia with the distal pin in either the os calcis or the tibia. This entire "mechanical hand" may be raised or lowered on the telescoping supporting column (G). Flexion or extension of the knee is thus obtained, controlling the tension of the gastrocnemius group of muscles, which play an important part in supporting the fragments. The base may be adjusted to accommodate legs of different lengths and to permit the use of a short traction screw. Construction is such that there are no removable small parts such as nuts, bolts or thumb screws, and there is no need for the use of wrenches or other tools. Moving parts are protected from plaster and dirt by covers.

Fig 3—The patient shown in figure 2 fourteen days after fracture. The covered ends of the pins are clearly visible. This patient weighed 220 pounds (100 kg).

ROUTINE PROCEDURE

1 A local anesthetic is injected into the fracture hematoma and at the pin sites.

2 One-eighth inch steel pins are inserted at the level of the tibial tubercle and through the body of the os calcis. No incisions are made, so that the surrounding skin snugly grasps the pins. Dressings are unnecessary. The os calcis is preferred to the lower tibial fragment as the site for the distal pin, because traction exerted on the heel corrects foot drop and prevents sagging of the fragments by maintaining the tension of the calf muscles.

6 Griswold, R. A. Surg., Gynec. & Obst. 58: 900-902 (May) 1934.

3 The base of the apparatus is adjusted to the distance between the pins and the pins are inserted in their respective calipers, which are in neutral position

4 The upper calipers are pivoted to bring the proximal fragment into the axis of the apparatus

Fig 4—Condition of bones of patient shown in figures 2 and 3 fourteen days after fracture and ten days after start of ambulatory treatment.

5 The length of the limb is restored by tightening the traction screw

6 The distal fragment is aligned by the worm and rack adjustment

7 Rotary displacement is checked. This usually corrects itself if allowed freedom of action and merely requires locking in position

8 The traction is reduced slightly to allow firm contact of the fragments

9 The position is checked by roent-

genograms or the fluoroscope and any necessary residual corrections are made (fig 2)

10 If there is minimal soft tissue damage, a cast is applied from the toes to the upper part of the thigh, firmly incorporating both pins. As soon as the plaster has set, the limb is removed from the apparatus, the ends of the pins are covered with corks and plaster, and a walking iron is incorporated (fig 3). In most cases it is wise to leave the extremity in the apparatus for from forty-eight to seventy-two hours before applying the cast. This prevents circulatory embarrassment from swelling

Fig 5—Type of cast used for convalescent support

COMPOUND FRACTURES

Compound fractures are treated under spinal or general anesthesia. Pins are inserted and the extremity placed in the apparatus in a routine manner. Pinpoint wounds compounded from within out are

treated with an antiseptic and a light dressing. Procedure is then carried out as for a simple fracture. All other compound wounds seen within eight hours are thoroughly debrided, irrigated with from 4 to 10 liters of physiologic solution of sodium chloride and the skin is closed tightly. Wounds more than eight hours old but not grossly infected are debrided and packed open with petrolatum gauze. Badly infected wounds are packed but not debrided. Reduction is completed by the

apparatus without levering or manipulating the bones in the wound. All patients receive prophylactic doses of gas and tetanus antitoxins. The leg is left in the apparatus until the condition of the soft parts warrants application of a cast. This is usually a week or ten days

AFTER-CARE

Ambulatory treatment with weight bearing is started as soon as the cast is dry. Crutches are used at first, to be exchanged for a cane at the end of a week or two. Later no external support may be necessary, and the patient can often resume his or her usual occupation (figs 3 and 14). The pins remain in place until the cast is changed at about eight weeks. At this time a

Fig 6—Fracture compounded by direct violence in patient 3½ years old. Dirt was driven deeply between the fragments.

new cast is applied as high as the tibial tubercle or the upper thigh, according to the site of fracture and the progress of union. This cast takes the place of the usual convalescent brace until unprotected weight bearing is safe (figs 5 and 9)

RESULTS

From July 1, 1933, to June 1, 1934, eighty patients with fracture of the shaft of the tibia with or without fracture of the fibula were admitted to the Louisville City Hospital. Eleven died within forty-eight hours of shock and associated injuries, such as fractured skull or crushed chest. No deaths occurred later than within forty-eight hours. Five were transferred elsewhere

Fig 7—Wound illustrated in figure 6 ten days after débridement and closure showing primary healing. Ready for cast and walking iron

after first-aid treatment. The remaining sixty-four patients had sixty-seven fractured legs. The severity of the injuries seen is illustrated by the fact that the fibula as well as the tibia was fractured in sixty of these and twenty-nine were compound. One primary ampu-

tation was carried out for a shotgun fracture with complete destruction of the blood supply. Our reluctance to perform primary amputation perhaps explains the one subsequent amputation and one death from gas infection.

Two of the remaining twenty-eight compound fractures were badly infected on admission and were treated by petrolatum gauze packs. Three pinpoint wounds were not debrided and twenty-three larger wounds were debrided and closed. Of the twenty-six wounds treated by the closed method, eighteen healed by first intention. There were four mild soft tissue infections, and devital-

house staff of the Louisville City Hospital under only moderately strict supervision. The results are, I feel, a tribute to the enthusiasm and diligence of the three assistant residents and the six interns who have rotated on the fracture service during the past year.

CONCLUSIONS

1. Accurate mechanical reduction with skeletal control and fixation of both fragments makes early ambu-

Fig. 8—Condition of bones of patient shown in figures 6 and 7

lized skin flaps sloughed in two cases, all without osteomyelitis. One amputation was necessary for impaired circulation and sepsis after closure. One death occurred thirty-six hours after the accident from gas infection. The last two cases probably represent ill advised

attempts to save badly mangled extremities. Of the sixty-six extremities treated, the apparatus and double-pin technic were considered advisable in forty-three. The remainder, with less severe injuries, were treated by manual reduction, plaster cast and walking iron. Eleven fractures did not show firm union at the end of three months. Eight of these were compound injuries, two badly comminuted fractures of the middle third, and one a spiral oblique fracture of the lower third. Three of these

Fig. 9—Supporting cast applied after removal of first cast and pins seven weeks following fracture

have healed following persistent ambulatory treatment and there is definite roentgenologic and clinical evidence of eventual firm union without operation in the others. Hospitalization, including both simple and compound fractures, has been reduced to an average of less than ten days.

Most of the actual treatment of these cases, such as reduction and debridement, was carried out by the

Fig. 10—Severe compound (automobile bumper) fracture in an arterio-sclerotic man aged 54. Debridement and closure with sloughing of skin flap. Ambulatory treatment from fourteenth day following fracture illustrates overextension which resulted in delayed union.

latory treatment possible in fractures of the tibia and fibula.

2. An apparatus is presented to aid in attaining these ends.

Fig. 11—Spiral oblique (torsion) fracture which is easy to reduce but difficult to maintain by conventional methods. Firm dependable fixation with ambulatory treatment obtained by two pins incorporated in cast.

3. Properly performed debridement and primary closure is feasible in fresh compound fractures.

4. The results of this method of treatment in a crowded city hospital service have been acceptable.

ABSTRACT OF DISCUSSION

DR. W. BARNETT OWEN, Louisville, Ky. The first point for consideration is careful selection of cases in which fixed traction is to be applied. It is necessary to apply the fixed apparatus properly, make a careful roentgen study before and after application, and note the reduction. Then, as in all types of fractures, comes the consideration of the maintenance with the least inconvenience and expense to the patient. That is an item of importance because of lack of money. Since this type of cast was adopted, the hospitalization has been reduced 80 per cent, which is quite a saving. The careful debridement and primary

closure in compound fractures is a problem in which uncommon sense must be used. One can get into a great deal of trouble unless one's judgment is very good, and even then will probably get into trouble sometimes. I am enthusiastic about this method of treatment because I think it disables the patient for a very short time and all know the advantage of ambulatory treatment provided the maintenance of the fracture line is observed. No patient is discharged from the hospital if there is any question of any disturbance of blood or nerve supply. Patients are carried on and observed in the clinics and followed up in the social service.

DR J A CALDWELL, Cincinnati. The ideal method of treating any fracture is to reduce it accurately and hold it in position until healing takes place. When great comminution or obliquity of fragments makes it impossible to maintain reduction, some method must be used to hold the fragments from the outside or from the inside. About the simplest way that I know of is to put two pins through the bone above and below the fragments and fasten them to two bars, which extend parallel to the bone, and later incorporate those pins in plaster. That is the method carried on by Dr Griswold. After the fracture has been held that way, if the patient can then be made ambulatory, the time of hospitalization and of disability is reduced because it does away with much softening from inactivity and also keeps up the patient's morale. This method has been used at the Cincinnati General Hospital in thirty-seven cases. The results

Fig 12—Reduction obtained in automobile bumper fracture

have been comparable to those Dr Griswold has shown. The apparatus that has been used has been somewhat simpler—the ordinary Thomas splint can be used. Two lugs are clamped to the sides of the splint and the pins are fastened to these and traction is made by pulling on the lower pin. After the leg has been pulled out to proper position and the fragment has been reduced, as shown by the roentgenogram, the lugs are tightened to the bars of the splint and left that way. Rotation can be obtained by putting one lug above and one lug below. With this simple device one can get accurate results in from a week to ten days depending on whether or not the fracture is compound or simple, or swelling has subsided. My associates and I are in the habit of cutting off the pins and letting the patient go home with the pins incorporated. We haven't used ambulatory casts to the extent Dr Griswold has, largely through excessive caution. Since seeing how Dr Griswold carries his work and how the hospitalization of his patients is reduced, it is only a matter of time when we shall adopt his method.

DR MAXWELL HARBIN, Cleveland. Years ago, when the Abbott apparatus was devised for leg lengthening, it occurred to me that it would be a satisfactory type of apparatus for treatment of these fractures. At that time I felt that it was necessary to have two pins above and below the fracture site to control angulation. It is interesting to see Dr Griswold control the anterior-posterior angulation so satisfactorily with only two pins. I am wondering whether that will be universally true. He has a large enough series of cases here to indicate that it is possible. I would question the necessity of the torsion adjustment. It would seem that fragments can be easily aligned to

normal rotation relationship at the original application of the pin. I still believe in the use of some padding of the plaster splints, where there is a rapid turnover of the house staff, particularly in the hospitals since every precaution against the possibility of soft tissue damage should be taken. This is not necessary in the hands of one who carries through the care of these cases alone.

Fig 13—Comminuted fracture with no contact between proximal and distal main fragments. Ambulatory treatment without displacement

DR F G MURPHY, Chicago. I wish to emphasize still further the use of the walking iron in these cases. The stimulation of function does more to produce union and promote union than any other factor, and that includes accurate immobilization. In cases in which apparently there is delayed union, if the stimulation of function is given and walking with a properly fitted cast, many will go on toward union.

DR RALPH G CARROTHERS, Cincinnati. I have used this method a number of times and found it satisfactory. There are two types in which it is applicable. One is the long spiral fracture, which will override with any type of retentive apparatus I have seen except this. In that type of case it is excellent. I think that casts must be made nonpadded because, as these two pins are parallel to each other, the bones can act as spokes in a wheel, using the pin as an axle, and if the cast has too much padding in it that is what will occur, with sores on the skin occurring more readily than if the cast is nonpadded, holding the fragments rigidly still. In the compound fracture,

Fig 14—Patient shown in figure 13. Preexisting genu varum maintained

however, I do not close with plaster for several days, and there I think the double pin method is astoundingly good. I have had recently a case of gangrene develop. It was in an arm, not a leg. The same method was used, the same principle. Once this infection had started, I could not have been able to put in pins because I had a swollen member. Having put my pins in I could leave them and I had all sides of that arm to work with. I could split the fascia both fore and back and was able to clean

up the gangrene infection and not get the pinholes infected. The patient went home, a month after the onset. I feel that any other method would have ended disastrously.

Dr. Edson B. Fowler, Evanston, Ill. I want to put in one word of warning on closing these wounds when they are badly comminuted and compounded. Instead of closing, it has been my practice to enlarge the wound and leave it wide open. I am in thorough accord with Sherman of Pittsburgh, who never closes such wounds and who told me that he never had an infection develop.

Dr. R. A. Griswold, Louisville, Ky. In this series, including compound and simple fractures, the period of hospitalization was an average of eight and one-half days per case. That runs about five days for the simple fractures and something between ten days and a little over two weeks for the compound. There has been no trouble with the nonpadded cast so far in the hands of interns. It has been used under mild supervision and it is surprising how little trouble has occurred. There have been fewer pressure sores than from the padded casts. I think Dr. Caldwell's apparatus is the simplest and most effective. On the question of gas gangrene, prophylactic doses of gas and tetanus antitoxin are being used in all compound fractures that are being closed or left open and treated with the ordinary method.

SILICOSIS AND PRIMARY CARCINOMA OF THE BRONCHUS

REPORT OF CASE

M. JAMES FINE, M.D.

AND

JAMES V. JASO, M.D.

Phthisiologist and Assistant, respectively, Newark City Hospital

NEWARK, N. J.

Pneumoconiosis includes all forms of pulmonary fibrosis occurring as a result of the inhalation of organic or inorganic dust. It is definitely an occupational disease and is rare outside of large industrial and mining districts. The group comprises

- 1 Anthracosis—*inhalation of coal dust*
- 2 Siderosis—*inhalation of iron and steel dust (usually by metal grinders and polishers, nail and file makers, and so on)*
- 3 Chalicosis or silicosis—*inhalation of stone dust (usually by stone workers, such as potters, grinders, plasterers, porcelain makers or quarry workers)*

This report is concerned with chalicosis or silicosis.

Under normal conditions the lung is fairly well protected from ordinary amounts of city dust. This protection is effected by the action of the ciliated epithelium, phagocytes, mucous secretions, and the cells of the bronchial tubes. However, in persons who work in atmospheres heavily laden with dust these protective mechanisms are insufficient and depositions of the particles occur. As a result, destruction of the epithelium takes place and the subsequent desquamation permits the entrance of these particles into the lymph stream, where they are carried to peribronchial and mediastinal nodes, connective tissue structures, perivascular organs and even distant tissues, there producing definite pathologic changes. A person who works for any length of time in dusty trades will develop some fibrosis of the lungs sooner or later, the extent varying according to the susceptibility of the individual. Some workers after years of exposure show no evidence of impairment of health, while others succumb early to pulmonary changes. Insanitary conditions and faulty nutrition are probably factors in the early development of these changes.

SYMPTOMS AND SIGNS

The clinical symptoms depend on the cause, the extent and the duration of the process. Stone dust is likely to produce symptoms earlier than coal dust will, but the patient does not show incapacity until after years of exposure. The earliest symptoms are those of chronic bronchitis. The cough at first is unproductive but later is accompanied by expectorated material, which is stained gray, black or red and which contains the inhaled material. Prolonged coughing leads to pulmonary emphysema with dyspnea and asthmatic symptoms. Wheezing and shortness of breath may constitute the predominant features of these conditions. Microscopic examination of the sputum shows the offending particles lying free in the cells.

The physical signs are those of chronic bronchitis, pulmonary emphysema, fibrosis and bronchiectasis. In the earlier stages only signs of bronchitis are found. Later, respiratory movements become restricted and the patient appears to be in respiratory distress, especially on exertion. Vocal fremitus and the percussion note become impaired only when marked induration and bronchiectatic cavities have developed. In the earlier stages, coarse mucous râles are present, subsequently, bronchovesicular and bronchial breathing with sibilant râles, prolongation of expiration and the characteristic wheezing sounds of the asthmatic patient develop.

DIAGNOSIS

The diagnosis is based on the history of long continued exposure to a dust laden atmosphere and the subsequent development of the symptoms and signs enumerated. Careful, repeated examination of the sputum should be done. Typical cases should show no evidence of the tubercle bacillus. Particles of the causative agent, such as stone, steel, iron and coal, will be found in the sputum. The condition, once it has become well advanced, is not responsive to treatment.

The case to be reported is of particular interest because, in spite of a preliminary diagnosis of advanced tuberculosis, we could find no evidence of this condition and on the basis of the history and physical examination a diagnosis of silicosis was made. The patient's condition was complicated by an overlooked and unsuspected primary carcinoma of the bronchus.

Primary carcinoma of the lungs is said to occur usually in middle life and is more frequent in males. Trauma and irritation from dust inhalation have been cited as causes. The right lung appears to be the seat of the tumor more often than the left. Tuberculosis may be associated with carcinoma, although not often in the same lung. Primary carcinoma is considered rare. The symptoms vary with the location and size of the tumor. A cough is usually early and constant but may be absent in rare instances. It is unproductive, often paroxysmal and distressing. When the growth involves the trachea or large bronchus, the symptoms are aggravated. Expectoration is rarely profuse and consists of a small amount of mucous or mucopurulent material. The sputum may be dark red or brownish, from admixture with blood. Profuse hemoptysis however is rare, although shreds of carcinomatous or sarcomatous tissue are occasionally found in the sputum. Pain varies with the involvement of the pleura or mediastinum and the amount of pressure exerted. Dyspnea is usual and early, but chills and sweats are uncommon. Loss of weight and strength, anemia, cachexia and emaciation occur as the disease advances, probably as

much because of the cough, dyspnea and anorexia as because of the absorption of toxic material. Examination reveals modification of the normal outline, with a bulging or a general enlargement of one side. Occlusion of a large bronchus may lead to collapse or retraction of the lung and to an actual diminution in the size on the side affected. Restriction of respiratory movements is an early and constant sign. Dilatation of the superficial veins of the chest, especially the upper part, is common. As the growth increases in size, the signs of circulatory obstruction become evident.

The aggregation of symptoms pointing to primary carcinoma of the bronchus is known as "Weller's¹ syndrome." In the order of frequency the signs comprising this syndrome are a cough, dyspnea, expectoration, hemoptysis, thoracic pain and pressure manifestations.

Wolf² thinks that scar formation from previous syphilitic infections or other causes may predispose to this condition. He also mentions a tendency of the hard enlarged bronchial glands to break through into the bronchi and considers that soot and dust from these may act as tissue irritants leading to slow continued inflammatory changes.

Adler³ explains the preponderance of cases in the male on a vocational basis. He points out that males are more often engaged in occupations and habits that irritate the bronchi than are women.

Occasionally trauma has occurred prior to the onset of symptoms and may be cited as a possible factor. Pathologists are reluctant to consider trauma as a defi-

cases of primary pulmonary carcinoma were found in 1,900 necropsies.

It was early suggested that the lesions of tuberculosis might give rise to changes in the structure of the lung and its accessory tissues, which might develop into tumors. An analogous process has been described in chronic tuberculous ulcers of the skin, and it was considered reasonable to assume a similar development in the lung. However, the infrequency with which tuberculous processes have been found in carcinomatous lungs in recent reports is striking. Some authors feel that direct trauma, in which bruising of the pulmonary tissues occurs, may be related to neoplasms of the lung. This has not been well substantiated by fact. Cases

Fig 1—Right lung showing primary carcinoma of bronchus. The roughened nodular carcinomatous infiltration of the mucosa of the main bronchus producing slight stenosis may be noted. The carcinoma in this case started in the main bronchus outside the lung.

Differential Diagnosis

	Tuberculosis	Silicosis	Primary Carcinoma of the Bronchus
History	Exposure to tuberculosis	Exposure to dust	Irritation, trauma and so on (negative)
Fibrosis	Gradual	Gradual	Slight
Cough	Productive	Dry, hard, distressing	Early but not productive
Sweats	Nocturnal	None	None
Weight	Early loss	Late loss	Late loss
Hemoptysis	Early	Late	Late
Dyspnea	Gradual, slow	Progressive	Late from obstruction
Fever	Afternoons	None	None
Cavities	Form late	Form late	Do not form

nite cause, but many recent observers feel that this association may be of more importance than has previously been recognized.

The differential diagnosis between silicosis, carcinoma and pulmonary tuberculosis may be summarized as in the accompanying table.

Primary carcinoma of the lung is now found in about 1 per cent of all cases coming to necropsy. Thirty years ago it was observed in not more than 0.2 per cent of necropsy material. This may be due to an actual increase in the number of patients suffering from this disease or to improved methods of study and earlier diagnosis. In a thousand necropsies reported by Klotz and Simpson⁴ for 1910, only two cases were found. From 1910 to 1920 the reported incidence at necropsy was 0.5 per cent. During the last six years, nineteen

in which there appears to be some association between the trauma and the tumor are very rare. The most widely discussed tumor whose development is related to the presence of dust in mines is that occurring among the Schneeberg miners, in whom an unusually high incidence of pulmonary carcinoma is found. In this region the cobalt mines contain iron, bismuth, nickel, zinc, lead and tin in combination with arsenic and sulphur. The ore is radioactive and its complexity offers a field of rich and interesting speculation.

In the last few years we have examined twenty-one cases of silicosis. The majority of the patients died of complicating tuberculosis, which is prevalent among patients with this type of pneumoconiosis. In one of these cases, in which no tuberculosis was present, a malignant tumor had developed in one lung. The presence of carcinoma of the lung in association with silicosis appears to be of such importance as to merit comment and report. At present, silicosis is one of the important occupational diseases of the miners of northern Ontario, and although few die of the pneumoconiosis itself, all are liable to premature incapacitation through tuberculosis, heart disease or pulmonary infections. Observations on the joint existence of cancer and silicosis are too few to permit conclusions.

New York: Longmans, Green & Co. 1912.

⁴ Lubmann, E. Silicosis and Carcinoma of the Lung. In Klotz, O. and Simpson, W. *Ann. vol. 2* page 685 (1932).

From our review of the literature it appears to us that 5 per cent of all cancers originate in the lungs. The growth is more common on the right side, probably because the main bronchus is shorter, wider and more vertical on that side than on the left. It is about one-third as common as carcinoma of the stomach. It is becoming increasingly apparent that primary bronchogenic carcinoma is to be considered as a common, rather than a rare, form of tumor.

REPORT OF CASE

History—P. A., a white man, aged 52, married, was referred by the medical department to the chest clinic with a diagnosis of advanced pulmonary tuberculosis. He was first seen by us in May 1933, at which time he complained of a dry hacking cough, loss of weight and dyspnea. He had been a stone cutter for twenty years. His habits were moderate, his living conditions good. He smoked a pipe but not to excess. He had abandoned his work three years before we first saw him but in spite of rest, relaxation, idleness and nourishing food his condition had become worse. The cough was now productive and he had lost 15 pounds (6.8 Kg.) during the past year. He complained of moderate dyspnea but did not have night sweats or hemoptysis.

Examination—The man was emaciated, the ribs were prominent. Chest expansion was poor and limited on both sides. No visible pulsations were noted. Vocal fremitus was somewhat increased on the right side. Many moist rales were heard throughout the chest. At the right apex the breath sounds were cavernous, but there were no definite crepitant rales. The heart showed some evidence of myocarditis but there were no murmurs or enlargement.

The urine was normal. The Wassermann reaction was negative. The sputum was examined repeatedly, but tubercle bacilli were never found. However, pus cells were found in abundance in every specimen of sputum.

Course—Jan. 18, 1934, the patient was admitted to the Newark City Hospital because the dyspnea had become so severe as to require oxygen therapy. January 21 there were signs of pulmonary edema with coughing spells. At this time

No fluid was found in the right pleural cavity. However, numerous old adhesions over the upper lobe, laterally and at the apex, were found.

The left lung was large, with a hyaline-like, almost cartilaginous, thickening of the visceral pleura over the upper lobe. The hilar nodes were anthracotic, with a calcified node 1 cm in size. The lung was a slate gray and showed small nodules distributed chiefly over the upper lobe and upper half of the lower lobe. On cutting, the organ was firm and leathery and

Fig. 4—Section of lung showing silicosis. Typical silicotic nodules with surrounding fibrosis may be noted.

no cavities could be found. Innumerable small nodules of sandlike bluish gray, slate color were found over the entire parenchyma. In places they were confluent with an acinous-like arrangement.

The upper lobe of the right lung was almost entirely fibrotic. At the apex a cavity about 1.5 cm in diameter with necrotic walls was found. The hilus showed numerous, large, anthracotic lymph nodes, some of them a distinct slate color. Projecting into the lumen of the mass starting just below its bifurcation was an elevated, roughened, nodular, reddish gray area, which occupied a position practically at the opening of the large bronchus. This infiltration extended down the wall of the bronchus for a considerable extent and slightly into the surrounding lung tissue. No large lung tumor was found.

On microscopic examination, the mass in the right main bronchus proved to be a primary carcinoma. The histologic picture was a mixed one, most portions showing an arrangement of cancer cells distinctly squamous in type, classifying the growth as epidermoid carcinoma of the bronchus. In the deeper portions, however, the growth was more anaplastic and undifferentiated and distinct of the small cell type. Sections from the lung parenchyma showed extensive silicosis, with the formation of typical silicotic nodules with concentric laminations.

CONCLUSIONS

1 One must not make a hasty diagnosis of tuberculosis because a patient has symptoms suggesting pulmonary tuberculosis, without careful study.

2 A careful history in this case would have suggested a diagnosis of silicosis rather than tuberculosis.

3 The similarity of symptoms in the early stages of pulmonary tuberculosis, silicosis and primary carcinoma of the bronchus renders the diagnosis somewhat difficult.

4 Bronchoscopic examination early in this case would have revealed the new growth.

Figure 2

Figure 3

Appearance nine months (fig. 2) and one month (fig. 3) prior to death. In figure 2, extensive silicotic nodules throughout both lungs also extensive atelectasis of upper part of right lung, probably due to stenosis of right main bronchus. In figure 3, almost identical changes.

the sputum was blood streaked. The temperature fluctuated between 99 and 104 F. The patient died in March.

Necropsy—The costal cartilages were excessively soft.

The left pleural cavity contained about a pint of yellowish fluid. Old adhesions were found over the lobe, laterally and at the apex.

5 The necropsy and the pathologic examination were done by the chief county medical examiner Dr. H. S. Martland, to whom we are indebted also for the photomicrographs.

5 This carcinoma is by far the commonest variety. More than 90 per cent of cases fall into this group. The tumor is obviously bronchogenic, commencing in a bronchus and spreading along the bronchial tree and into the lung substance. It may originate in the bronchus outside the lung. The lesion without the bronchus varies from a mere roughening of the mucosa to a complete stenosis.

6 Primary carcinoma of the bronchus in conjunction with silicosis is comparatively rare.

7 All workers whose occupation entails exposure to the dust hazard should have their chest roentgenographed at the start of work, and at periodic intervals thereafter.

COMMENT

There appears to be no report in the literature of cases demonstrating the coexistence of primary carcinoma and silicosis in the lung. The reason for reporting this case is that we are of the opinion that the combination of the two diseases is not uncommon and that its apparent rarity is due to the fact that an insufficient number of cases of silicosis come to necropsy.

These occupational dusts are chemical irritants. In the light of our knowledge of the role of chemical irritants in the causation of cancer, it is not inconsistent to expect silicosis to be followed by carcinoma occasionally.

Clinical Notes, Suggestions and New Instruments

RECTOURETHRAL FISTULA WITH INVOLVEMENT OF PROSTATE AND SEMINAL VESICLE

J J VALENTINE MD AND JOHN W ROGERS MD
NEW YORK

Although fistulous tracts involving portions of the urinary apparatus are relatively common, this case report would seem to be of particular interest because of the unusual course of the fistulous tract, its chronicity and rare clinical manifestations, the difficulties presented in arriving at not too certain a preoperative diagnosis, and its satisfactory outcome.

REPORT OF CASE

G R, a man, aged 40, whose wife had never become pregnant and whose family history is irrelevant, at the age of 5 had to be catheterized three or four times a day for retention of urine. This persisted for a period of six months, when a spontaneous discharge of pus through the rectum relieved the urinary retention and thereafter he was able to void voluntarily. He stated that for many years following he experienced no difficulty. He never acquired a venereal infection. He married at the age of 24 and immediately thereafter his present illness began.

At this time and during the next few years, at intervals of about every three or four years, he suffered with attacks of pain and a feeling of fulness and swelling in the rectum, accompanied by hematuria. He was relieved by bladder and rectal irrigations. One attack eight years ago apparently was more severe than the previous ones and, as he did not obtain relief from the treatment that he had received, a friend suggested that he drink whisky. He followed this advice and was surprised to note that his symptoms subsided in the course of a few days after the consumption of only 2 quarts of this palatable remedy. Four years before we saw him he experienced another severe attack of pain with terminal hematuria, but he stated that whisky did not relieve him and, instead, a left epididymitis developed. With this he observed cloudy

urine, which was thick and purulent at the terminal period of urination. Again he was relieved by palliative treatment.

During the next three or four years he was examined in several clinics and by various urologists in the city and with

Fig. 1—Retrograde pyelogram, right side, demonstrating large normal right kidney and absence of left kidney shadow.

eager cooperation received all manner of diagnostic procedures and treatment, with no relief of symptoms.

This brings the history to November 1931, when he came under our observation.

Immediate History and Examination—The patient complained of a sense of fulness in the region of the prostate and

Fig. 2—Recent repetition of intravenous urography again demonstrating nonappearance of opaque solution in left kidney area.

a feeling of discomfort along the left spermatic cord. He experienced painful contracture, deep in the perineum, at the end of the act of urination. There was no urgency or increased frequency of urination. He voided a free stream, the urine

was malodorous and cloudy in the first two glasses, but the terminal spurts were very cloudy, containing many bloody shreds. The left testicle was atrophied. Otherwise the genitalia were normal.

The prostate was somewhat enlarged, firm and sensitive. A sausage-like mass was felt to run transversely across the right prostatic lobe and backward toward the rectum. The right seminal vesicle was thickened, indurated and sensitive. There was much periprostatic infiltration, and a small dimple-

Fig. 3—Urogram of right vas, demonstrating blockage of retrograde opaque medium at approximate position of upper margin of right seminal vesicle.

like intrusion was felt on the anterior rectal wall at the level of the base of the right prostatic lobe.

The voided bladder urine showed a *Bacillus coli* infection and the prostatic smear was loaded with pus.

Cystoscopy revealed an increased prostatic intrusion, a normal appearing bladder mucosa and the absence of a left ureteral orifice. Suspecting the possibility of a left ureter emptying into the urethra or seminal vesicle, intravenous skiodan films were made. These apparently proved the absence of a left kidney and ureter. The function of the right and solitary kidney was normal and its urine was uninfected.

Eliminating upper urinary tract infection, we focused our studies on the urethra and by endoscopy a small gaping orifice was seen on the right side of the posterior urethra between the sphincter and the verumontanum. Many pus flakes were seen discharging from this orifice, and an increased flow of pus could be produced by making pressure on the right lobe of the prostate. Several attempts were made to introduce a small catheter or bougie into this opening, without success. A few cubic centimeters of opaque solution was injected into this opening through an ejaculatory duct cannula, but the solution regurgitated anteriorly and the procedure did not assist us, in conjunction with roentgenograms, to establish the course of the fistulous tract.

A right vasotomy was then performed and a solution of skiodan injected into its lumen with the hope of establishing the patency of the vas, as well as possibly to outline by x-rays the course of the tract. These plates showed the vas to be blocked at about the position of the upper end of the right seminal vesicle.

Urethrograms were likewise of no help. Several proctoscopic examinations were reported negative, and no methylene blue from the urinary tract appeared in the rectum.

After these detailed examinations the patient was kept under strict observation and it was noted that about every two or

three weeks the voided urine would become clear and during these periods he would invariably complain of pain, fullness in the rectum and prostate, general malaise, and fever as high as 103.5 F, accompanied by chills. Suddenly he would void very foul urine, full of pus and blood as well as particles of fecal matter, and at times observe blood in the stools. Immediately following the discharge of this extremely foul material he would feel well again. We noted this phenomenon at least four times in four months.

In view of these symptoms, together with our urethroscopic, roentgen and rectal observations, a diagnosis of the presence of a chronic fistulous tract between the rectum and the posterior urethra, involving the prostate and seminal vesicle, was made and operation was advised.

Operation and Result.—The prostate and seminal vesicles were exposed through the usual perineal incision. The space between the rectum, urethra and bladder, involving the prostate and right seminal vesicle, was occupied by dense, fibrous, inflammatory tissue. This area, which contained at least a portion of the fistulous tract, was removed by sharp dissection as close to the rectum and urethra as safety would permit. The right lobe of the prostate was further incised for drainage. Two large cigaret drains and two small soft rubber tubes were placed deep into the wound, which was then packed with petrolatum gauze. On removal of the Crowell retractor from the urethra a small gush of urine appeared in the wound, suggesting that there either must have been some trauma to the urethra, caused by the retractor or made during our dissection, or that the urine escaped from the urethral end of the fistulous tract. An indwelling catheter was anchored in the bladder through the urethra.

Pathologic examination of tissue removed showed chronic purulent inflammation with no evidence of tuberculosis or a malignant condition.

The postoperative course was normal. The catheter was removed on the seventh day and the patient voided voluntarily. There was some leakage of urine into the wound for a few days, after which it healed firmly.

Fig. 4—Apparent course of fistulous tract.

His present condition is satisfactory in all regards. Urinations are normal, with clear urine. His general health is good and his sexual function, although disturbed for a time following the operation, is now greatly improved.

CONCLUSION

1. We believe that, when the patient was a child, an abscess of unknown origin and exact location ruptured into the rectum or urethra, or both, and that a small tortuous fistulous tract communicating with these organs resulted.

2 The occasional temporary closure of the fistulous tract caused retention of infected material within the abscess cavity, and there being no drainage, the urine would appear clear. Absorption produced the systemic and local manifestations that he experienced such as general malaise, fever, chills and pain. As soon as drainage reestablished itself, though the urine became foul containing pus, blood and fecal matter, he invariably felt better.

3 The cure resulted from the complete excision of the area of chronic inflammatory tissue traversed by the fistulous tract

ACCIDENTAL OVERDOSE OF PHENOLPHTHALEIN IN A CHILD WITHOUT THE EFFECTS

WILBERT SACHS MD JERSEY CITY N J

W H Jr, a boy aged $3\frac{1}{2}$ years of Jersey City, was given for the first time on the night of June 24 1934 one chocolate laxative tablet containing phenolphthalein. The following morning at 8 o'clock the child got to the household medicine cabinet and, finding the tin that contained the tablets ate all of the remainder contained in the box. One hour later he was discovered by his mother who noted that his lips and face were smeared with chocolate and that all the tablets were gone. The child had therefore apparently consumed the total contents of the container, altogether forty-eight tablets. Although the child seemed perfectly well the mother gave him an enema, following this the bowels moved at intervals of half an hour, five times in all. She then took the boy to the Jersey City Medical Center, where he was admitted to the pediatric service.

The temperature on admission was 100 F, but the pulse was good. The child vomited several times after admission and had two bowel movements. There was no blood in the stool. The urine was passed in normal amounts and showed no albumin, sugar, casts or blood. No tests were made for phenolphthalein in the urine and stool but the vomitus showed a few pieces of the tablets.

The temperature was normal the following day. There was no further diarrhea or any other abnormality such as a skin eruption or sore mouth to be observed. The child was discharged on the third day. No medication was given while the child was in the hospital. A bland diet had been ordered.

A sample tablet of this laxative was found to contain 2 grains (0.13 Gm) of phenolphthalein and, as the tin bought by the mother contained forty-eight of such tablets, the amount taken by the child totaled 96 grains (6 Gm). Judging from reported cases, this is the largest amount of phenolphthalein taken as an overdose.

The child was subsequently observed in the outpatient department of the hospital. One urine specimen was said to have contained blood (examination at a commercial laboratory) but several twenty-four hour specimens examined at the hospital laboratory shortly before this and also later in another laboratory, showed the urine to be normal. Several blood counts, one immediately after discharge and one a week later, showed nothing abnormal. A test for phenolphthalein in the urine and stool one week after the child was discharged from the hospital failed to show the presence of phenolphthalein.

COMMENTS ON LITERATURE

Sollmann¹ believes that the systemic disturbances reported following the use of phenolphthalein are doubtful in nature. Cleeves,² however, reported a fatality in a boy, 10 years old, who had accidentally taken 18 grains (1.2 Gm) of phenolphthalein in the form of laxative tablets. In this connection it is interesting to note an article by Vamossy,³ who introduced phenolphthalein as a laxative thirty years ago. After carefully reviewing the clinical history and postmortem examination in the case reported by Cleeves, Vamossy states that the febrile

and hemorrhagic toxic symptoms described had nothing whatever to do with phenolphthalein and that one is dealing with a severe toxic effect due to a cellular poison—bacterial or spoiled foods—that manifested itself coincidentally with the taking of phenolphthalein. Vamossy does not believe that his colleagues will accept a report based on post hoc ergo propter hoc evidence such as was submitted by Cleeves.

In the same article, Vamossy calls attention to the various cases of skin eruptions that have been caused by the use of phenolphthalein. Such eruptions however he believes are very rare and are found in persons who have an allergic hypersensitivity to phenolphthalein.

There are a number of instances reported in which a large overdose of phenolphthalein has caused no alarming symptoms or subsequent ill effects.⁴ There are no doubt still others in which large overdoses were taken accidentally but were not reported because nothing of any importance developed.

The absence of ill effects in my case after an overdose of 96 grains as well as the numerous other instances in which large overdoses had caused no ill results lends support to the view of Vamossy and others who are convinced that phenolphthalein does not produce harmful disturbances in man.

GNADOTROPIC AND ESTROGENIC PRINCIPLES IN A MYOMA OF THE UTERUS

DEAN LEWIS MD AND CHARLES F GESCHICKTER MD
BALTIMORE

In a paper recently published we described a fibro-adenoma of the breast which when assayed, yielded a relatively great amount of estrogenic principle. Because of this finding we were prompted to assay a uterine fibroid to determine whether the estrogenic principle, the follicle-stimulating factor and the luteinizing principle might be found in this type of tumor.

A hysteromyomectomy was performed on a patient whose history will be given later.

The fibroids were removed, care being exercised that no mucous membrane was included in the tumor. The material was forwarded to Dr J H Morrell of the E R Squibb and Sons Laboratory for a bio-assay. Dr Morrell reported that the tissue contained $4\frac{1}{2}$ rat units of the follicle-stimulating and luteinizing factors per gram of desiccated tissue. The extract of the tissue gave both effects. This material was tested by the same technicians who are standardizing the preparation of the anterior pituitary-like gonadotropic principle from the urine of pregnant women and they reported nothing different from the usual effects. The estrogenic test of this material shows that it contains 4 units per gram of tissue or the equivalent of about 1,800 units per pound.

We can find no record of a bio assay being made on a myoma for these substances. Ammon has shown that the differential diagnosis between large myomas and pregnancy can be made by the Aschheim-Zondek test. He reported twenty-four negative tests in suspected myomas. In twenty-two cases the results of the tests were verified by operation. The urine of these patients did not contain the luteinizing principle. DeFermo has reported the occurrence of the follicle-stimulating factor in the urine of patients with myoma.

The history of the patient from whom the fibroid was removed is as follows. B P, an obese colored woman, aged 34, began to menstruate when she was 12 years old. The menstrual cycle was of the twenty-eight day type, was regular, and lasted four days. The last period began on Aug 10 1934. A hysteromyomectomy was performed, August 28. The patient com-

plained of pain in the back and lower part of the abdomen, which began about a week before the operation. Examination revealed hypertension. An abdominal tumor could be palpated, which extended from the brim of the pelvis to within three fingerbreadths of the umbilicus. The blood pressure was 155 systolic, 108 diastolic, the weight, 222 pounds (101 Kg.), the Wassermann reaction, 4 plus. The vaginal examination revealed a mucopurulent discharge and a lacerated cervix. The fundus of the uterus contained many myomatous nodules. The patient became pregnant in 1915 and again in 1916. Abortions were induced, one at the third month and again during the fourth month.

The pathologic examination revealed submucous, interstitial and subserous myomas of the uterus, chronic endometritis, chronic bilateral salpingitis, a right parovarian cyst, chronic, left perioophoritis and chronic appendicitis.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—Ed.

THERAPY OF BEDSORES

PROPHYLAXIS

The occurrence of a bedsore is generally a reflection on the quality of the nursing service, excepting in those cases of almost unavoidable bedsores the prevention of which tests the prognostic acumen and the therapeutic resourcefulness of the physician, as the acute decubitus, occurring sometimes even within a few hours of the onset of transverse lesions of the spinal cord (e. g., myelitis), and the subcutaneous bedsore, occurring in the depth of the anal fold in severely toxic patients with profound nutritional disturbance.

Of the two factors in the production of bedsores, the extrinsic and the intrinsic, the former is in all cases except the two types mentioned the most important one. These extrinsic factors are (1) prolonged pressure, (2) maceration and (3) traumatism, all of which must be scrupulously avoided. Even in those cases in which the intrinsic factor of lowered tissue vitality is prominent, extraordinary care in the avoidance of the extrinsic factors is generally all that can be done and is often sufficient.

1. Prolonged pressure on any part of the patient's body, but most especially over bony prominences such as the sacrum, the scapulae, the heel, ankles and elbows must be prevented. Normally, whether awake or asleep, a person rarely rests in one position for any length of time. When, because of disease or of the necessities of treatment, this primitive human instinct is thwarted, three things must be substituted for it: change of posture, distribution of pressure, and maintenance of the best possible circulation over the pressure points.

Frequent change of posture is perhaps the most important of these, not only to forestall bedsores but also to prevent hypostatic pneumonia. As long as the

patient voluntarily changed his posture, the ancient physician was hopeful for him, when he did not, he considered it a bad omen. The nurse would do well to make a record of the fact that "the patient does not change posture" and do this for him. When the requirements of therapy forbid such change of posture, all the other prophylactic factors must be employed with extra zeal.

Minimizing the pressure over the bony prominences, particularly the sacrum, is only second in importance. The best means for this purpose is the water cushion, an almost bed-width square, placed in the middle of the bed with pillows above and below. This should be employed in all especially threatened patients, as in those with transverse myelitis, even before signs of "threatened" bedsores manifest themselves. As a patient with transverse myelitis may develop a bedsore even during a long trip to the hospital, preventive treatment should be practiced during such transportation. The water cushion is filled with water at 95° F. to such tension that, when both hands and arms are used, effort is necessary to press the sides of the cushion together. It is covered with a sheet. If a water cushion is not obtainable, an air mattress serves fairly well. Small air cushions or rubber rings, which should be but moderately inflated and covered smoothly with clean linen, such as a pillow slip, are inferior to the water cushion. "Cotton doughnuts" (cotton rings made of the size required and to fit parts of the body where pressure is likely to produce sores) must be improvised when other means are not available. Not only should the sacrum be cushioned, but the next most threatened part of the body, the heels, should also be kept from the pressure of the bed by means of a circular pad under them. Still better is a large firm pillow placed under the knees, which also maintains flexion of the lower extremity and prevents the painfulness that tends to develop in the limb when it is kept in constant extreme extension. A rubber pillow case should always be employed to protect the pillow. If a rubber pillow case is not available, one may use as a substitute a small blanket roll covered with a piece of muslin. These are easily laundered.

As backache tends to develop whenever a patient must lie on his back day after day, or even more rapidly when the lumbar muscles are completely relaxed, as after anesthesia, the cushion under the sacrum should be placed so as to preserve the "hollow of the back." A person who has lost the lumbar curve of the spine has a "weak back," is likely to suffer from a tendency to backache on slight fatigue, and is prone to develop painful sprains of the sacro-iliac joints from minor jars to the body, all of which might have been prevented by a cushion under the upper part of the sacrum during prolonged sickness.

To improve the circulation in the tissues of the back, the back rub is the most important aid. Every bed patient is entitled to it at least once a day, preferably at bedtime. Patients who are acutely ill should be given at least two back rubs a day, and those who are very ill should receive the back rub still more frequently, as often as the bedding is changed, if the patient is incontinent, and after the back has been washed thoroughly. The back rub is nothing more or less than massage, and a well planned and skilful application of it is, of course, better than planless rubbing, though the latter is better than no rubbing at all. The back is best massaged with the patient lying on one side, the patient being turned toward the nurse,

so that if he is weak one arm may support him while the other does the rubbing. A little 50 per cent alcohol is poured on the hand from time to time and the rubbing is continued until the alcohol has evaporated. The direction of the movements is from the base of the skull downward, and the manipulations consist of a stretching of the tissues away from the spinal column. In any one region, long effleurage strokes may be practiced first and last, with kneading or friction movements in between. These are performed by holding the hand in firm contact with the patient's skin and moving the flesh on the bone. If the patient is stout or the tissues are firm, the one hand may be reinforced by placing the other on it. The movements should be smooth and uniform, not jerky or choppy, and their rhythm slow if sedation is aimed at more rapid if stimulation is desired. The back rub is finished by pouring a little talcum powder or zinc stearate on the hand and rubbing this on the skin.

Alternation of heat and cold is also of value in stimulating the local circulation. As cleanliness is godliness itself in the prevention of bedsores, the back may have to be washed many times a day and each time one should follow the use of the hot water (105 F) by rubbing the back with a dash of cool (50 per cent) alcohol until the skin is dry and red, finishing with talcum powder.

PRESCRIPTION 1—Back Rub Salve

R	Zinc stearate	5 00 Gm
	Tincture of benzoin	5 00 cc
	Scarlet red ointment 5 per cent	0 25 Gm
	Hydrous wool fat	30 00 Gm
	Liniment of camphor	180 00 cc
	Mutton tallow	500 00 Gm

Melt the fats add the camphor liniment, and when the mixture has almost cooled, beat in the tincture of benzoin and the zinc stearate until a creamy mixture is secured.

Label: After each cleansing apply a very small amount of this ointment during the back rub if the skin is harsh and excessively dry (to prevent bedsores).

2 Maceration of the skin from sweat, urine, fecal matter or pus must be prevented at all costs, for maceration makes the skin extremely vulnerable. Waterproof material, such as a mackintosh, under the draw sheet, while it may be of value in protecting the mattress, predisposes to maceration of the skin. The most important thing, when the patient has involuntary urination or defecation, is to place under the patient an abundance of absorbent material, such as an oakum pad with a foundation of several thicknesses of newspapers and to change this immediately when it becomes soiled or wet. If the patient is restless, the pad is kept in place by a three cornered piece of muslin put on like a child's diaper. The divided mattress and, in cases of children with involuntary urination, the Bradford frame are valuable aids.

3 Trauma, even a little scratch, may be the determining factor that permits the invasion of the ubiquitous bacteria. Crumbs have an almost malignant tendency to accumulate under the part most threatened with bedsores, hence they must be looked for after every meal and brushed out thoroughly. The draw sheet must be pulled tight and the body clothing kept smooth, for even a wrinkle may cause an abrasion that is followed by a bed sore.

If the skin is harsh and excessively dry, it is well to rub on after each cleansing a very little Hydrous Wool Fat or a back rub salve (prescription 1), much in favor with the bedside nurse. The liberal smearing on of ointments is not permissible, as they tend to cause maceration of the skin.

TREATMENT

Three possible conditions must be distinguished, as they require different therapeutic tactics. A Threatened bed sore. B Unavoidable bed sore. C Ulcer.

A The physician who does not on his daily round examine the back of the very sick patients who are especially predisposed to bedsores is remiss in his duty. The threatening bed sore is indicated by cutaneous erythema that disappears on pressure. If they have not yet been instituted, the prophylactic measures that have been discussed must now be developed to their full

PRESCRIPTION 2—Alum Alcohol

R	Alum	30 00 Gm
	Water	250 00 cc
	Alcohol	250 00 cc
		to make

Dissolve the alum in the water and add the alcohol.

M Label: Apply to part subjected to pressure to prevent bedsores.

extent. In addition, the skin should be (a) hardened if it is soft, or (b) have a protectant applied to it, if it is harsh and dry. Moist compresses or salves are still taboo at this stage.

(a) For hardening, the skin may be painted with 5 per cent solution of Silver Nitrate in Distilled Water. This is also useful when there are small breaks in the skin. A saturated solution of Alum in Diluted Alcohol (prescription 2) should be applied during the back rub several times daily after cleansing.

(b) For protection, a piece of moleskin adhesive plaster serves quite well, provided the skin under its edges is examined daily to make sure that there is no irritation, or else a dressing of Flexible Collodion painted over the surface may keep a harsh, dry skin from cracking.

B The stage of unavoidable bed sore is made evident by the fact that pressure no longer drives the redness from the congested part. Efforts must now be concentrated on minimizing the damage by a strict enforcement of the principles of prophylaxis, with the addition of the tannic acid warm air treatment.

(a) Tannic Acid Warm Air Treatment. A 5 per cent aqueous solution of tannic acid is sprayed on the uncovered area, which is kept dry by turning the patient so that the affected surface is exposed to the warm air under an electric light cradle. If a blister is present, the elevated epidermis is removed aseptically and the raw surface sprayed every hour until a heavy protective coagulum has been formed. (For details of this treatment see Therapy of Burns.)

PRESCRIPTION 3—Thymol Iodide-Ferrous Sulphate

R	Thymol iodide	
	Exsiccated ferrous sulphate	of each 25 00 Gm

Mix Label: Apply liberally to affected surface. As soon as the ferrous sulphate produces a burning sensation blow off the excess of powder leaving only a thin adherent film. Cover with dry absorbent gauze held in place by strips of adhesive plaster. Renew dressing when ever it becomes moist at least once in forty-eight hours for not more than six or eight applications. (To secure dry gangrene.)

(b) Dusting Powder. If it is impossible to place the surface so as to give it the benefit of the warm air treatment, efforts should be concentrated on securing dry gangrene by the liberal use of Thymol Iodide or some other impalpable antiseptic dusting powder. If there is a great tendency to moist gangrene, the drying effect may be greatly increased by use of the thymol iodide-ferrous sulphate powder (prescription 3). When a line of demarcation has formed and the slough loosens, it is gently and aseptically removed by scissors and forceps.

(c) Moist Treatment. This is indicated only in bedsores by the evidence of spreading infection or of

retained pus. Then warm Boric Acid compresses must be used after any fluctuating area that is present has been incised and these continued until the slough has been shed and a clean ulcer secured. Irrigations or dressing with Surgical Solution of Chlorinated Soda (Dakin's solution) hasten the separation of the slough. The continuous bath is, however, the best method of treating this serious complication and should be resorted to whenever the previously suggested measures do not secure a prompt improvement.

C The ulcer resulting after separation of the slough is treated according to the principles of ulcer therapy (q v).

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER, Secretary

BIOLITE INFRARED GENERATORS ACCEPTABLE

The McIntosh Electrical Corporation, Chicago, Illinois, manufactures and offers for sale the following infra-red radiation equipment:

Biolite Infrared Generator, Senior Model including three generating units, 900 watt capacity, automatic timer unit shipping weight 125 pounds.

Biolite Infrared Generator Junior Model including Senior Biolite Infrared Generating Unit 600 watt capacity shipping weight 40 pounds.

Biolite Infrared Generator Home Model including Senior Biolite Infrared Generating Unit 300 watt capacity shipping weight 30 pounds.

In general, the construction of the heating element of these three models is common to all. This heating element is made of a lava support or spool, around which is wound the required amount of resistance wire. Finally, the spool and wire are wrapped with monel metal. The finished heating element is about 2 inches long and about 1 1/4 inches in diameter. The size, however, depends on the rating.

In the Senior Model, three elements are connected parallel and supported on a bracket in such a manner that each element hangs 120 degrees from its neighbor. The entire assembly is connected to a socket so that it can be screwed into the reflector. The reflector of the Senior Model is 12 1/4 inches in diameter, nickel plated inside, and black enamel without. The reflector and heating unit are mounted on a counter balance cross arm so that a good deal of leeway is permitted for the adjustment to the height of the burner. The reflector also swings at the end of the cross arm. The entire unit is mounted on a substantial base equipped with rubber tired casters and the whole unit may be moved conveniently from place to place.

The Junior and Home Model Infrared Generators make use of one resistance heating unit, each differing only in capacity. The diameter of the Junior Model Reflector is 11 inches and of the Home Model 9 inches.

One of each type of unit was examined in a laboratory acceptable to the Council. The Senior Model was connected to a 110 volt alternating current circuit and the current required read 7.75 amperes. At a distance of 1 meter from the edge of the reflector, the radiant energy within a circle 1 meter in diameter was explored with a thermopile and galvanometer. A reading on the galvanometer showed that within a circle of 70 cm in diameter the average energy was about 13 per cent more than at the periphery.

When the Junior Model was connected to a 118 volt alternating current circuit, the ammeter read 4.2 amperes. Exploring the radiant energy distribution of a circle 70 cm in diameter, directly in front of the reflector and 1 meter from its edge, revealed that the average energy distribution in the center was 26 per cent more than at the periphery. When the Home Model was connected to a 113 volt alternating current line, the ammeter read 2.7 amperes. Exploring the radiant energy distribution within a circle 70 cm in diameter, directly in front

of the reflector and 1 meter from its edge, revealed that the energy distribution in the center was 15 per cent more than at the periphery. In the opinion of the Council, these units will render satisfactory service in hospital, clinic or office, or wherever heat therapy is indicated. The Council, therefore, voted to include the three Biolite Infrared Generators in its list of accepted devices.

Council on Pharmacy and Chemistry

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT

PAUL NICHOLAS LEXCH, Secretary

DIHYDROXY-ANTHRANOL (ANTHRALIN)

This preliminary report is authorized by the Council at the request of the Section on Dermatology and Syphilology in order that Stokes et al., whose observations are hereinafter discussed, may present their report before a section of the Scientific Assembly.

Dihydroxy-anthranol, submitted by the Abbott Laboratories, has been employed as a substitute for chrysarobin in the treatment of various skin disorders. The same compound was originally introduced into dermatology about 1916 under the trade name "Cignolin." Its formula is $C_{14}H_{10}O_3$ and, structurally, appears as

Fig. 1—Dihydroxy anthranol
Cignolin

Fig. 2—Chrysophanic acid

Although there is some dispute concerning the formula for chrysarobin, it is fairly certain that it consists in part (at least 30 per cent) of a methyl ester of anthranol of the structure reproduced in figure 2.

It is claimed (Unna) that removal of the methyl group results in greatly decreased toxicity, particularly with regard to constitutional reactions following absorption from the skin (nephrosis, gastro-intestinal irritation, and so on). Its further advantages over chrysarobin lie (1) in the ready manufacture of the product (by reduction of dioxanthraquinone, an easily available substance used in industry), (2) in its definite chemical composition, (3) in lessened liability to production of dermatitis, (4) in its failure to produce conjunctivitis when used about the face or scalp, and (5) in the very slight discoloration produced.

The Abbott Laboratories has suggested the name Anthralin as a nonproprietary designation for dihydroxy-anthranol. The Council voted to accept this nonproprietary designation. Anthralin is a yellowish crystalline powder, practically insoluble in water but readily soluble in the more complex organic and lipid solvents—a feature of distinct advantage in the preparation of ointments, lotions and pastes. Its color is probably least noticeable in petrolatum album, which provides for it an economical and satisfactory ointment base.

Anthralin has been used only for external application in concentrations of from 0.1 per cent to 5 per cent, a very weak preparation always being used at first, however, and the strength being increased according to the tolerance of the patient. Compounds of from 0.5 to 1 per cent have usually been found optimal.

Studies of the effect of the drug in psoriasis, pityriasis rosea, seborrheic dermatitis and mycotic skin infections have been quite extensive. European observers have been particularly exhaustive in their observations in psoriasis. Notable among these many workers are Unna, Galevsky, Meierowsky and Strebel, Bruck, Kretschmer, Ihle, Brinitzer and Böttstern,

Biolite
Infrared
Generator

Sundeck, Roth, Schaffer, Bergner, Pollard, Ullmann, Ludwig, Prowaty, Grunich, Huck Luth, Kronmeyer and Kennedy all of whom regard Anthralin as most useful. Certain of these dermatologists consider the drug equally valuable in fungous infections of the skin and at least one (Kronmeyer) considers it of outstanding value in pityriasis rosea. One hundred and twenty nine cases of superficial fungous infections were reported cured by Prowaty (1920) using 0.25 per cent dihydroxy-anthranol from two to three times daily at intervals of two or three days. Satisfactory though probably not unusual therapeutic results have also been reported in sycosis, alopecia areata, lichen simplex chronicus, lichen planus, lupus verrucosus, deslucium capillitii ulcus cruris, impetigo herpes, acne indurata folliculitis and parapsoriasis.

The commmication from Beermann, Kulehar Pillsbury and Stokes involves use of the drug in fifty resistant cases of psoriasis of from five to twenty years duration. Of all these cases only two had been completely cleared by various combinations of the following modes of therapy: low nitrogen diet, coal tar ointment, ultraviolet irradiation, ammoniated mercury and salicylic acid ointments, autohemotherapy, x-radiation, arsenic compounds, chrysarobin, potassium iodide, balneotherapy. With dihydroxy anthranol, twenty three cases exhibited complete involution within four months, fifteen showed from 80 to 90 per cent involution within three months, seven demonstrated from 40 to 70 per cent involution in one to four weeks. Only one patient remained resistant, and even in that case, although the lesions on the legs remained unaffected, the body condition cleared 50 per cent. Of twenty-nine cases of psoriasis of the scalp, eighteen underwent complete involution, seven showed 80 to 95 per cent involution and the remaining four from 30 to 70 per cent improvement. The use and effectiveness of Anthralin in disease of the scalp is particularly significant, since chrysarobin, by reason of its conjunctival irritation, can not be so employed.

Although the Council appreciates the vast foreign work that has accumulated regarding dihydroxy-anthranol, it has deferred consideration of Anthralin until such time as more adequate investigations of the nature, properties and pharmacologic and toxic actions of the drug shall have been reported.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. RAYMOND HERTWIG, Secretary.

- (1) GOLD BOND BRAND WHITE SYRUP
- (2) JACKSON'S SPECIAL BRAND GOLDEN TABLE SYRUP

Distributors—(1) Milburn Johnston Grocer Company, Ken-sett, Shirley and Searcy, Ark., and Harrison Grocery Company, Monett, Mo., and Harrison and Cotter, Ark. (2) Standard Grocery Company, Indianapolis.

Packer—D B Scully Syrup Company, Chicago.

Description—(1) Table syrup, corn syrup base (85 per cent) with rock candy syrup (15 per cent). The same as White Crystal Table Syrup (85 per cent Corn Syrup 15 per cent Rock Candy Syrup) Flavored with Vanilla and Coumarin. THE JOURNAL, April 15, 1933, page 1174.

(2) Table syrup corn syrup base (85 per cent) with refiners' syrup (15 per cent). The same as Banner Blue Corn Syrup with Cane Flavor, THE JOURNAL, March 5, 1932, page 817.

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

Packer—Bliss Syrup and Preserving Company, Kansas City, Mo.

Description—(1), (3) and (5) Table syrup, corn syrup flavored with refiners' syrup.

(2), (4) and (6) Table syrup, corn syrup sweetened with sucrose syrup and flavored with vanilla.

Manufacture—(1), (3) and (5) The same as Bliss Pancake Brand Golden Syrup (THE JOURNAL, Oct. 28, 1933, p. 1393).

(2), (4) and (6) The same as Bliss Pancake Crystal White Brand Syrup (THE JOURNAL, Nov. 18, 1933, p. 1635).

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

VETA-CRISP LOGS

Manufacturer—Battle Creek Biscuit Company, Battle Creek, Mich.

Description—Milk chocolate coated biscuit prepared from milk chocolate, white flour, sucrose, hydrogenated coconut butter, skim milk, cocoa, malted milk, wheat bran powder, egg yolk powder, sodium chloride, ammonium bicarbonate, and sodium bicarbonate.

Manufacture—Soft wheat flour, powdered skim milk, egg yolk powder ammonium bicarbonate, sodium bicarbonate and sodium chloride in definite proportions are automatically mixed, pumped on to baking plates and baked in a rotary oven. The finished sheet of cracker is placed on spreaders and the filling, comprising powdered sucrose hydrogenated coconut butter, skim milk, cocoa, malted milk, bran powder and sodium chloride, is spread on in three layers, and the sheet is cut into bars which are chocolate covered, cooled, inspected, and packed in boxes or small packages wrapped in cellophane.

Analysis (submitted by manufacturer) —	per cent

KRIM-KO'S FIVE-O CHOCOLATE FLAVORED SWEETENED DILUTED SKIM MILK

Bottler and Distributor—J A Schultz and Sons, Big Flats, N Y.

Licenser—Krim-Ko Company, Chicago manufactures the Five-O Chocolate Flavored Drink Base and licenses its use, the name Five-O, and standard advertising under definite contract conditions.

Description—Sterilized chocolate flavored sweetened diluted skim milk containing skim milk, water, sucrose, chocolate and cocoa, tapioca flour, salt and a trace of agar, flavored with imitation vanilla extract. See Krim-Ko's Five-O Chocolate Flavored Sweetened Diluted Skim Milk THE JOURNAL, June 23, 1934, page 2105.

SATURDAY, JANUARY 5, 1935

SELENIUM PROBLEM

Selenium is an unusual element, and little is known concerning its distribution and actions. Since Frank traced the cause of an animal disease known locally as "alkali disease" to the vegetation grown on certain definite soil areas, and the U. S. Bureau of Chemistry and Soils subsequently detected selenium in the vegetation of these areas, interest has been definitely aroused. The presence of selenium has been traced from plant to soil and from soil to parent shales. Among the shales known to contain selenium is the Pierre shale, in certain sections of which occur nodules of iron pyrites. One of these nodules was found to contain 205 parts per million of selenium. Williams and Byers¹ examined soils and shales from various regions for selenium content. From the quantitative results obtained, selenium is of much wider distribution in soils and vegetation than has heretofore been suspected. Probably in arid and semiarid areas the presence of selenium is to be expected in every case in which the sulphur content of the soil parent material is high. The derived soils and their vegetation may contain sufficient selenium to render them potentially dangerous, but the mere presence of selenium in soil is not to be considered an indication of an inferior soil. Soils produced in humid areas, according to this report, are not likely to have a pernicious selenium content even though the parent materials are relatively rich in this element.

Knight² has extended these observations in a recent report before the Association of Official Agricultural Chemists. It has been demonstrated, he states, that the toxicity of the vegetation grown on soils containing selenium is proportional to the selenium content. Thus, wheat grown by the Bureau of Plant Industry on artificially selenized soil was toxic to rats and guinea-pigs. The Bureau of Animal Industry demonstrated that the symptoms of "alkali disease" may be produced in pigs

by administering selenium in the form of inorganic compounds. The Bureau of Home Economics has shown that symptoms can be produced in small experimental animals corresponding to those produced by feeding forage grown on selenized soils. Corresponding symptoms are produced by feeding inorganic selenium compounds.

In certain localities the plant growth on seleniferous soil may be sufficiently toxic to produce acute symptoms and fatal results in a brief interval, so that one opportunity to consume such vegetation may prove fatal. In other areas, more chronic symptoms may be produced by consumption of less toxic vegetation. So far as is known at present, the extremely virulent vegetation is produced for the most part on nonarable lands and therefore the effect is confined to grazing animals.

While the investigations are not far advanced, it would appear that quantities of selenium compounds insufficient to produce toxic symptoms do interfere with the growth, development and normal increase of animals consuming them. In all cases the toxic effect is especially injurious to young animals. These facts may prove of immense importance not only in this country but also in other countries, since the semiarid areas of the world constitute the great wheat producing areas. Indeed, it has been demonstrated already that appreciable quantities of selenium are found in grain derived from foreign sources. There is no occasion, however, for undue anxiety. Only a few cases of injury to man as a direct result of poisoning by selenium-bearing vegetation have been definitely determined and in none of these apparently has the result been fatal. The greatest injury so far demonstrated, in fact, has been the reduction of the profit in livestock raising. Here the losses have been so great as to cause the abandonment of farms and ranches, though the source of trouble was often unsuspected or improperly assigned.

The particular selenium compounds have not yet been isolated and identified, but it is known that selenium occurs in the soil in both inorganic and organic forms. In the plant and animal tissues it is present in at least two different types of compounds. In wheat grains it appears to be concentrated for the most part in the gluten of the wheat and in general in the protein portion of seeds. In this form it is essentially insoluble in water. The seleniferous compounds in growing plants, however, may be brought into aqueous solution. In the animal organs the maximum concentration has been found in the liver.

Some conception of the magnitude of the relatively new problem of distribution and toxicity of selenium compounds is now available. Much remains to be done. Knight lists some of the more pressing problems: the isolation, identification and synthesis of the organic selenium compounds developed by plants, determination of the products of these compounds which result from digestion, determination of the question whether sele-

¹ Williams, K. T., and Byers, H. G. Occurrence of Selenium in Pyrites, *Indust. Chem.* 6: 296 (July 15) 1934.

² Knight, H. G. The Selenium Problem: address before the Association of Official Agricultural Chemists, Oct. 30, 1934, Washington, D. C.

num is cumulative in the animal body or whether in the processes of metabolism its course follows that of sulphur, studies aimed at clinical diagnosis of selenium poisoning and the remedial measure to be employed, the disposition of lands injuriously affected by selenium, and the establishment of scientifically sound study of the physiologic and pathogenic effects of organic selenium compounds

RELATIONSHIPS AMONG THE STEROLS, ESTROGENIC SUBSTANCES AND CARCINOGENIC COMPOUNDS

The isolation¹ in crystalline form from pregnancy urine of substances with estrogenic activity and the subsequent elucidation of the structure of these compounds have demonstrated a constitution similar to the sterols and bile acids, to the testis hormone and to certain carcinogenic materials. The existence of these similarities in molecular configuration has led to attempts to obtain evidence for functional relationships in the living animal and has produced unusually interesting results. In general, it appears that the physiologically active members of these groups of substances consist of a phenanthrene molecule with a five membered ring attached to one end of the molecule, and that various polar groups, side chains and double bonds are possibly associated with different types of activity in the various molecules. Certain other products isolated from pregnancy urine have structures which suggest that these compounds may be intermediates in the degradation of the body sterols, principally cholesterol, into the so-called sex hormones.

Knowledge of the constitution of the estrogenic hormones has resulted in attempts to obtain synthetic materials with estrogenic activity. It has actually been possible in one instance to produce a compound in the laboratory which has even greater physiologic activity than the naturally occurring theelin from pregnancy urine. This achievement is significant from an organic chemical standpoint, as it demonstrates how physiologically active compounds can be produced in the laboratory. Fully as important is the doubt these observations throw on the question of the specificity of hormones. The original concept emphasized the extreme specificity of this group of chemical agents, the mere change from the naturally occurring optically active isomer of either thyroxine or epinephrine to the synthetic isomer results in a marked alteration in physiologic effect. Now, however, there appear to be compounds of somewhat differing structures which are capable of producing the whole phenomenon of estrus in mammals and even the feathering changes that can be induced in the male bird by injection of the crystalline compound from pregnancy urine.

As certain of the synthetic carcinogenic substances are known to contain the phenanthrene nucleus, experiments have been conducted to determine whether these compounds possess any estrogenic activity. Most striking is the observation that two of these compounds, 1,2-benzpyrene and 5,6-cyclopenteno-1,2-benzanthracene, are capable of producing a full estrous response by the injection of 100 mg. of either compound. These substances, therefore, exhibit the dual activity of carcinogenesis and estrogenesis. It should be emphasized, however, that the estrogenic power although definite is weak, and that the main pharmacologic actions of these compounds lie in their carcinogenic properties. It is evident, nevertheless, that the dual activity does exist.

Since the condensed carbon ring group of compounds under consideration also includes vitamin D or calciferol, investigations have been conducted on the estrus-producing activity of ergosterol, calciferol and related sterols. It was found that the greatest activity was possessed by neo-ergosterol, 40 per cent of the animals injected with this compound developed full estrus. Calciferol and ergosterol also exhibited estrogenic activity. It was further demonstrated that the estrogenic power of vitamin D appears to be quite apart from its power to raise the content of blood calcium. Here again therefore, is evidence that a single, naturally occurring molecule may possess at least two entirely separate physiologic effects, in this case antirachitic and estrogenic activity. It seems impossible at the present time to conclude that all the compounds which exhibit estrogenic activity are converted in the body of the castrate animal to theelin or theelol. In any event, these results further emphasize the importance of the sterol group in metabolism.

DERMATITIS FROM STOCKING "FINISHES"

Skin eruptions associated with the wearing of certain articles of clothing are not infrequently reported in medical literature. Frequently the cause of dermatitis produced in this way is correctly attributed to one or more of the dyes employed in coloring the fabric. Recently a report has appeared¹ which indicates that in certain cases the irritating agents may be substances employed to "finish" the cloth, that is, to soften the fibers or to give the fabric a "crunchy" texture. The finishes used on men's socks are said usually to consist of sulphonated oils or fats, ordinarily sulphonated castor oil or sulphonated olive oil, either alone or mixed with such products as mineral oils, unsulphonated oils and borax. Sulphonated oils are also employed on wool to "fluff" the material. Women's hosiery may be treated with starches, gums or gelatins or with japan wax, beeswax, paraffin or other waxes to render the fabric water repellent. In addition, inorganic salts such as zinc sulphate, barium sulphate, aluminum sulphate or titanium oxide may be used to diminish the luster.

¹ Extensive reviews of the literature are given by Stormer, Inge and Westphal, *Ulrich Ergebn. d. Physiol.* 35:318, 1933; Marrian, G. F., *Physiol. Rev.* 13:185 (April) 1933; Dodds, E. C., *Lancet* 1:931 (May 5) 1937; 987 (May 12) 1938; 1048 (May 19) 1934.

¹ Schwartz, Louis, *The Actual Causes of Dermatitis Attributed to Socks*, *Pub. Health Rep.* 49:1176 (Oct. 5) 1934.

Schwartz of the United States Public Health Service investigated four cases of dermatitis of the feet and legs attributed to the socks worn by the patients. The condition in one of these patients appeared to have been caused by a dye employed in coloring certain stripes in the rayon hose, the dermatitis followed the lines of the stripes. In the three other cases, not the dye but the finish appeared to be responsible. One patient had worn new unwashed black rayon socks, a fresh pair each day for four days. A fine erythematous rash developed over the areas covered by the socks, this disappeared within a week after the patient stopped wearing the latter on the advice of a physician. Patch tests with pieces of one of these socks produced severe dermatitis. The dye employed in coloring the hose was found to be "direct black," sold in this country to the extent of about 60 million pounds a year. Rayon fabric stained with this dye, but unfinished, was also used for a patch test, this gave no reaction. Another commonly used dye, "Zambesi black," similarly gave no reaction, but the patient proved sensitive to "sulphur black" and to "aniline black." Both these dyes were alkaline, as the finishes commonly used also are alkaline, these were next investigated.

The plant in which the hosiery in question had been made was located. These socks had been treated with a mixture of sulphonated castor oil and borax, with an alkaline preparation called "Sulphoricinol S" (the exact composition of which could not be obtained from the manufacturer) and with olive oil soap. The fabric of the sock contained 12 per cent of oil and enough free alkali to develop a pH of 7.8 in solution. Pieces of unfinished rayon dyed with direct black were immersed respectively in solutions of each of the two finishes and in one of olive oil soap. The pieces of cloth were then used for patch tests. The patient proved markedly sensitive to Sulphoricinol S, moderately sensitive to sulphonated castor oil and borax, and slightly sensitive to olive oil soap. As this indicated that it was the finish and not the dye that caused the dermatitis, the patient was told to wear one of these socks for several days after careful washing with soap and water and rinsing in clear water, dermatitis did not develop.

Schwartz reported two other cases in which it appeared quite probable that the finishes and not the dyes were the inciting agents. Two of the three patients were sensitive to alkali, as the finishes were alkaline, the base present probably caused the dermatitis in these cases directly. This author emphasizes the necessity for careful tests of the several agents used in the dyeing and finishing of clothing that may be involved in causing inflammation of the skin. He points out that it is important, particularly for allergic individuals, to wash off the finish and excess dye from new hosiery before they begin to wear it, manufacturers, he says, should use only minimal amounts of finishing substances, and these should be as nearly neutral in reaction as possible.

These studies demonstrate anew some of the hazards involved in the introduction into industry of new chemical agents for treating materials that come into direct contact with human beings. It is important that manufacturers should realize these hazards and that all new agents of this type should be adequately tested for toxicologic effects before they are adopted for use.

Current Comment

FIELD WORK IN CANCER CONTROL

The field work of the American Society for the Control of Cancer has been developed to spread knowledge and effect increased organization of the known means for combating cancer. The country has been divided into four districts for this work—Southern, Central, Northeastern and Western. The report¹ of the field representatives for these districts from 1931 to 1934 has recently appeared. The nature of the problems confronting the representatives varied considerably in different communities. The general plan of creating active interest in cancer control for a period of several years centering in the state medical society was followed in each instance. The program, stripped to its essentials, is well described by Dr. Cox, the representative for the Southern district. It consists in a cooperative effort on the part of three distinct units: (1) organized cancer clinics, special cancer treatment groups and unattached cancer specialists, (2) fourteen state medical societies together with their component societies, and (3) the lay group for which the American Society for the Control of Cancer is primarily responsible. The objectives toward which these groups are visualized as striving may be expressed as an enlightened lay group presenting itself either periodically or early, while the lesion is local, to a well informed family physician who is able to entertain suspicions, who appreciates his limitations and who will refer his pay and indigent patients to a competent group for diagnosis, prognosis and outline of treatment. The program of education, in its initial aspects, is concentrated on the medical profession. Lectures, symposiums, motion pictures, slides and literature are the best methods of spreading the latest knowledge of cancer control. Lay education is to follow with the adjustment of information to the technical knowledge of the general public. To those measures already outlined are added radio broadcasting, newspaper advertising and posters. Many ramifications are brought to light in the reports. Complications more or less general and some that are peculiar to special regions are also discussed by the representatives. When the high mortality from cancer, much of it preventable, is remembered, the value of this program should be easily manifest.

¹ American Society for the Control of Cancer. Report of Field Representatives, 1931-1934, Oct. 1, 1934.

Association News

THE ATLANTIC CITY SESSION Atlantic City Hotels

The Subcommittee on Hotels of the Local Committee on Arrangements has furnished a list of Atlantic City hotels and rates for rooms, which may be found on advertising page 33 of this issue of *THE JOURNAL* together with an application form that may be used to secure reservations through the Subcommittee on Hotels. The form that is printed in the advertising pages may be clipped and when properly filled in should be sent at once to Dr. William Edgar Darnall, Chairman of the Subcommittee on Hotels of the Local Committee on Arrangements, 16 Central Pier, Atlantic City, N. J.

If those who expect to attend the annual session of the American Medical Association will send in their applications at the earliest possible time, there should be no difficulty encountered in securing satisfactory accommodations. Applicants for reservations are especially requested to include a second and a third choice in order that good accommodations may be assured if the desired reservation cannot be had at the hotel of preference.

Symposium on Asphyxia and Anesthesia

At the Atlantic City session there will be a symposium in the Scientific Exhibit on asphyxia and anesthesia, composed of a group of exhibits on these two subjects. The symposium will be carried out in cooperation with the Society for the Prevention of Asphyxial Deaths which has appointed a special exhibit committee for this meeting and the Section on Anesthesia of the Canadian Medical Association, which will hold a session in conjunction with the Section on Miscellaneous Topics of the American Medical Association.

Application blanks for space in the Scientific Exhibit may be obtained by addressing the Director Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 central standard time. The next three broadcasts will be as follows:

January 10 Diphtheria Must Go W. W. Bauer, M.D.
January 17 The Good Old Days W. W. Bauer, M.D.
January 24 Progress Against Arthritis Irving S. Cutter, M.D.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15 central standard time. The next three broadcasts will be as follows:

January 8 Research in Abdominal Surgery Thomas S. Cullen, M.D.*
January 15 Causes of Death in 1933 W. W. Bauer, M.D.
January 22 Health in Winter W. W. Bauer, M.D.

*Dr. Cullen will speak from the National Broadcasting Company's Studios in Washington, D. C. by special arrangement.

Tremor of Spinal Origin—The simplest forms of tremor to understand are those of spinal origin. The fibrillary contractions of parts of various muscles, such as the first dorsal interosseus or the extensors of the fingers, or deltoid, that are so familiar in progressive muscular atrophy are clearly due to the progressive wasting of groups of anterior horn cells interrupting the rhythmic volley firing of the nerve cells and thus setting up irregular or incoordinate explosions of the clonic impulses resulting in visible contractions. Fibrillary tremors are thus a valuable clinical sign in the differentiation of progressive muscular atrophy of spinal origin from other forms of atrophy, such as the primary myopathies—Harris, Wilfred. Tremor, Ataxy and Spasm *Lancet* 2:1145 (Nov. 24) 1934.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS REFLECTING ON SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Clinical Meeting—The twelfth meeting of the Fort Smith Clinical Society, sponsored by the staffs of St. Edwards, Mercy and Sparks Memorial hospitals, took place November 22. In addition to clinics the following program was offered:

Dr. Miles F. Foster Recent Advances in the Treatment of Urinary Infections
Dr. Hardy H. Smith Jr. New Treatment of Gonorrhea in Children
Dr. Hubert C. Dorsey Control of Edema in Cardiac Decompensation
Dr. Frederick H. Knoch Uterine Cancer Surgery of the Corpus
Irradiation of the Cervix
Dr. Pierre P. Redman Present Status of Immunization Against Communicable Diseases
Dr. Tracey H. McCauley McAlester Okla. Pneumonia in Childhood
Dr. George B. Fletcher Hot Springs National Park Diagnosis and Treatment of Coarse Tremors
Dr. Lee Vallette Parmley, Little Rock Shock and Burns Due to Electricity

CALIFORNIA

Death of Dr. Martin—Ernest Gale Martin, Ph.D., professor of physiology, Stanford University School of Medicine, since 1916, died Oct. 17, 1934, aged 58. Dr. Martin had taught physiology at Johns Hopkins University, Baltimore, from which he received his advanced degree in 1904, Purdue University, Lafayette, Ind., and Harvard University, Sargent School for Physical Education and Radcliffe College, Boston. He served in the Sanitary Corps of the U. S. Army during the World War, was a member of many scientific societies and was author or joint author of several works on physiology.

COLORADO

Society News—Dr. Guy H. Hopkins addressed the Pueblo County Medical Society, recently, on "Atresia of the Lacrimal Duct in the New-Born."—Speakers before the Medical Society of the City and County of Denver, December 18, were Drs. Ward Darley, Jr., on "Primary Pulmonary Arteriosclerosis Associated with Habitual Ingestion of Large Quantities of Salt," Atha Thomas "Common Affections of Bursae," and Lyman W. Mason "Attempts to Correlate the Histology of the Endometrium with Theelin Concentration."—Dr. Edward Delehanty, Denver, addressed the Boulder County Medical Society in Boulder, December 13, his subject was "The General Practitioner as a Psychiatrist."

CONNECTICUT

Personal—A portrait of Leo F. Rettger, Ph.D., professor of bacteriology, Yale University, New Haven, was presented to the department by his friends and former students, December 1, at a meeting of the Connecticut River Valley branch of the Society of American Bacteriologists. *Science* reports. The portrait was made by W. S. Cummings of the Yale School of Fine Arts.

Society News—The Yale Medical Society was addressed recently by Dr. Joseph T. Wearn, Cleveland, on direct connections between the small arteries and the heart chambers, Dr. Ulrich Friedemann, formerly of the University of Berlin, recently addressed the society.—Dr. Murray B. Gordon, Brooklyn, addressed the Central Medical Society of Middletown, November 28, on "Endocrine Disturbances in Children."

DELAWARE

Surgical Conferences—November 2 marked the opening of a series of monthly surgical conferences by the Delaware Academy of Medicine, Wilmington, with Dr. George P. Muller, Philadelphia as the first speaker, on "Technical Procedure in Biliary Surgery." December 7, Dr. Damon B. Pfeiffer, Philadelphia, presented "Surgery of Cancer of the Colon" and January 4, Dr. Stanley P. Reimann, Philadelphia, "Tumors of the Breast." Others in the series include the following physicians:

Isidor S. Raydin Philadelphia February 7 Preoperative and Postoperative Management of the Handicapped Surgical Patient
Jacob Parsons Schaeffer Philadelphia March 7 Surgical Aspects of the Sympathetic Nervous System
William Wayne Babcock Philadelphia April 4 Operations on the Stomach
Floyd W. Keene Philadelphia May 2 Technical Procedures in Gynecologic Surgery
John F. Erdmann New York June 7 Acute Intestinal Obstruction

NEW HAMPSHIRE

Hospital Anniversary—The Margaret Pillsbury General Hospital, Concord, recently observed the fiftieth anniversary of its founding. The hospital is said to have been the first general hospital in the state. In 1890, George A. Pillsbury, Minneapolis, gave money for a new brick building, which was named in honor of Mr. Pillsbury's wife.

Society News—The dates of the next annual meeting of the New Hampshire Medical Society, which will be held in Manchester, have been changed to May 7-8.—Speakers at a meeting of the Rockingham County Medical Society, Brentwood Oct 25 1934 were Drs. Chester F. McGill, Portsmouth on "Pyloric Stenosis", Donald W. Leonard, Exeter, Use of Motion Pictures in Medicine", Gilbert L. Haggart, Boston, Management of Fractures," and Carleton R. Metcalf, Concord "Sickness Insurance".—Drs. Chester M. Jones and John Rock, Boston, addressed the Hillsborough County Medical Society, Nashua Oct 30 1934 on "Diagnosis and Treatment of Diseases of the Liver" and "Useful Endocrine Preparations in Endocrinology," respectively. Dr. Frederic P. Lord, Hanover, president of the New Hampshire Medical Society, made an address and Dr. Carleton R. Metcalf, Concord reviewed the subject of sickness insurance.—Drs. John J. Boardman, Hanover and Donald S. King, Boston, addressed the Grafton County Medical Society, Hanover Oct 13 1934 on "Uterine Hemorrhage" and "Newer Developments in the Treatment of Pneumonia," respectively. Dr. Frederic P. Lord, Hanover, president of the state medical society also made an address.

NEW JERSEY

Influenza Epidemic—Many schools in New Jersey were closed, December 18 and 19, because of an epidemic of influenza that swept through several counties especially in the southern part of the state, the New York Times reported December 19. The following figures were given for various areas: Collingswood 400 cases, Pennsauken Township, 500 cases, Ocean City 223 cases, Burlington Township 600 cases.

NEW YORK

Refraction for Indigent School Children—The Monroe County Medical Society is carrying out a special plan to provide eye examinations for a group of indigent children who could not obtain attention at hospital outpatient departments. A survey showed that 1,210 children were in need of refractions and that the hospitals would not be able to accommodate them for many months. The medical society in conference with the public safety and public welfare committees of the city council agreed to make the examinations for the sum of \$2,420 all to be completed by the end of 1934. Between September 15 and November 1, members of the society had completed 575 refractions. Glasses are to be furnished by the department of public welfare and various lay organizations.

Medical Library Presented to Hospital—A library of about 6,000 volumes and journals with an endowment of \$2,000 was presented to the Arnot-Ogden Hospital, Elmira, by the Elmira Academy of Medicine at a ceremony, November 22. The library was bequeathed to the academy by Dr. Hamilton Dov Wey as a memorial to his father Dr. William C. Wey, who settled in Elmira in 1849. It was for some time kept in the public library, but when lack of space made this arrangement impossible the books were placed in storage five years ago. Dr. Arthur W. Booth told the history of the collection and Dr. Ross G. Loop made the presentation, while Dr. George R. Murphy accepted for the hospital. The younger Dr. Wey served as senior physician at the Elmira Reformatory and as a member of the consulting staff of the Arnot-Ogden Hospital. Both father and son served as president of the Medical Society of the State of New York.

New York City

Scholarships for Graduate Study—A limited number of scholarships for qualified graduates in medicine who wish to do graduate study, especially in internal medicine are available at New York Post-Graduate Medical School, Columbia University. By the terms of the endowment, applicants from Allegheny County, Pennsylvania, will be given preference, other circumstances being equal. Application should be made to the director of the medical school, 303 East Twentieth Street.

Anniversary of Neurological Institute—Ceremonies in celebration of the twenty-fifth anniversary of the founding of the Neurological Institute of New York were held December 20. Speakers included Dr. Joseph Collins, one of the founders. Dr. Willard C. Rappleye, dean, Columbia University College of

Physicians and Surgeons, Dr. Bernard Sachs, past president of the New York Academy of Medicine, and Dean Sage, president of Presbyterian Hospital. A silver tray was presented to Dr. Collins as the sole surviving founder by Dr. Edwin G. Zabriske on behalf of the institute's staff. The Neurological Institute was opened in December 1909 through the efforts of Dr. Collins and the late Drs. Pearce Bailey and Joseph Fraenkel in an old building with antiquated equipment and eighty-three beds. The present building, with a capacity of 211 beds, was completed in 1929, when the institute became affiliated with the Columbia-Presbyterian Hospital Medical Center. In addition to caring for patients with nervous and mental diseases and training physicians in this specialty, the institute maintains a program of research in various fields.

Dr. Beeuwkes Awarded Medal—Dr. Henry Beeuwkes of the staff of the Rockefeller Foundation recently returned from England, where on November 6 he was awarded the Mary Kingsley medal by the Liverpool School of Tropical Medicine in recognition of scientific accomplishment in research on yellow fever conducted in West Africa. At the ceremonies in Liverpool, medals were awarded also to Sir George Buchanan, Sir Rickard Christophers and Sir Malcolm Watson. Dr. Beeuwkes was director of the West African Yellow Fever Commission, which studied yellow fever in Africa for nine years but which has recently been liquidated. He graduated from Johns Hopkins University School of Medicine in 1906 and then served a number of years in the medical corps of the U. S. Army, from which he resigned in 1924. The yellow fever commission was organized by the Rockefeller Foundation in 1925 with an original staff of ten members, under the direction of Dr. Beeuwkes. By the end of 1926 the laboratory was in operation with headquarters in Lagos, Nigeria. The commission from America worked in cooperation with the British government and its colonial officers, both in Nigeria and the Gold Coast. Some of the more important work of the commission includes:

1. The demonstration that the mild and widespread fever of West Africa is identical with the disease in South and Central America.
2. The susceptibility of *Macacus rhesus* and *sinicus* to the virus of yellow fever.
3. That the virus can be transmitted by *Aedes aegypti* and by numerous other varieties of mosquitoes.
4. That the cause of the disease is an ultramicroscopic virus.
5. That animals which recover remain permanently immune and their blood protects against the disease.
6. That protection tests based on the foregoing have made it possible to map out the past wide distribution and the limits of the disease in West Africa and have added much to our knowledge of the epidemiology of yellow fever.

Scientists who died from yellow fever acquired in Africa during this period of research include Dr. Hideyo Noguchi, Dr. Adrian Stokes and Dr. W. Alexander Young.

NORTH CAROLINA

Society News—Dr. Joseph B. Greene, Asheville, addressed the Buncombe County Medical Society, Asheville, December 3, on diagnosis and treatment of laryngeal tuberculosis.—A symposium on pellagra was presented before the Forsyth County Medical Society, November 13, by Drs. James C. P. Fearrington, William L. Kirby, Romulus L. Carlton and William D. Wylie, Winston-Salem.

Personal—Dr. Nathaniel T. Ennett, Mount Airy, has been appointed health officer of Pitt County, to succeed Dr. Robert S. McGeachy, Greenville, who recently resigned to go to Halifax County.—Dr. Sylvia Allen, Charlotte, recently gave a series of lectures at the Women's College of the University of North Carolina, Greensboro, on "Common Problems of Emotional Adjustments in College Students."

PENNSYLVANIA

New State Secretary of Health Appointed—Dr. Martha Edith MacBride-Dexter, Sharon, has been appointed secretary of health in the cabinet of Governor-Elect George Earle and will take office January 15. Dr. MacBride-Dexter was graduated from the Woman's Medical College of Pennsylvania in 1910 and practiced in Grove City and Erie before coming to Sharon in 1919. She is a member of the staff of the C. H. Buhl hospital and served for several years as secretary-reporter of the Mercer County Medical Society.

Philadelphia

Society News—The meeting of the Philadelphia County Medical Society, January 9, was called "Johns Hopkins Hospital Night" with the following speakers: Drs. Dean D. Lewis, professor of surgery at Johns Hopkins University School of Medicine, on "Surgery of Liver and Bile Passages", Arnold Rice Rich, associate professor of pathology, "Zonal Alterations

of the Liver Cells, with Reference to Hepatic Function", and Warfield T Longcope, professor of medicine, "Hepatic Necrosis and Cirrhosis with Some Reference to Chemical Substances as Occasional Etiologic Factors"

Medicodental Seminars—The Philadelphia County Medical Society and the First District Society of the Pennsylvania State Dental Society are sponsoring a series of lectures composing a symposium on "The Human Face" The lectures, which began January 4 and will continue through March 17, are on the following phases of the subject

January 4 Origin of the Human Face A Study in Evolution and Paleomorphology William K Gregory Ph.D., professor of vertebrate paleontology Columbia University New York

January 11 Ontogenetic Development of the Human Face, Dr Jacob Parsons Schaeffer

January 18, The Face in Its Developmental Career Milo H Hellman D.D.S., professor of dentistry, Columbia University School of Dentistry, New York

January 25 Roles of Heredity and Environment in Facial Development speaker to be announced

February 1 Human Facial Types Facial Expressions Dr Robert Tait McKenzie

February 15 Personality Types as Demonstrated by the Physiognomy speaker to be announced

February 22 Abnormalities of the Facial Development Due to the Endocrines speaker to be announced

March 1 Dynamic Physiognomy Dr Edward Lodholz

March 10 Facial Expressions Relating to Disease Dr George Draper New York

March 17 Facial Changes John V Mershon D.D.S.

In connection with these lectures there will also be afternoon clinics and round table discussions given by both physicians and dentists

Pittsburgh

Special Meeting of County Society—The Allegheny County Medical Society held a special meeting for a consideration of socialized medicine, December 28, at Carnegie Lecture Hall Dr George L Laverty, Harrisburg, chairman of the medical advisory committee to the state emergency relief board discussed 'Pennsylvania's First Year of the Emergency Relief Service' George R Harris, "How Health Insurance Has Worked in England and Germany," and Samuel B Goodstone 'The Proposed Health Insurance Bill of the American Association for Social Security'

TEXAS

Fort Worth Clinics—The semiannual Fort Worth Medical and Surgical Clinics were presented by the Tarrant County Medical Society, November 6 A clinical program of ten minute addresses was carried out during the day and an evening session followed a dinner for visiting physicians At the dinner session, addresses were made by Drs Charles T Stone, Galveston, on "Recent Advances in the Pathogenesis and Treatment of Diabetes Mellitus", Titus H Harris, Galveston, "Relation of Psychiatry to General Medicine," and Charles F Clayton, Fort Worth, "Orthopedics of Tomorrow"

VIRGINIA

Personal—Dr Edward M Holmes Jr, Norfolk, has been appointed assistant state epidemiologist—Rolland J Mam, Ph.D., has been named director of the department of physiology at the Medical College of Virginia, Richmond, during the leave of absence of Dr William R Bond—Dr Hunter H McGuire, Winchester, has been appointed a member of the board of visitors of the Medical College of Virginia, Richmond He was graduated from the college in 1897

Academy Members Honored—Four members of the Richmond Academy of Medicine who have been elected presidents of national medical organizations during the past year were guests of honor at a reception, November 27 A greeting was extended from the floor by Dr Stuart McGuire to Drs M Pierce Rucker, president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons Fred M Hodges, president-elect of the American Roentgen Ray Society J Shelton Horsley, president of the American Association for the Study of Neoplastic Diseases, and Robert C Bryan, president of the American Association of Genito-Urinary Surgeons

WEST VIRGINIA

Personal—Dr John William Moore is the new superintendent of Mountain State Hospital, Charleston—Dr George D Johnson, Huntington, has been appointed superintendent of the Spencer State Hospital, Spencer, to succeed the late Dr John E McQuain

Birthday Party for Dr Jacob Schwinn—The Ohio County Medical Society paid tribute to Dr Jacob Schwinn, Wheeling, at a dinner celebrating his eightieth birthday,

December 10, at the Fort Henry Club Born in Switzerland, Dr Schwinn was educated in Europe and has lived in Wheeling more than fifty years He has served as president of the Ohio County Medical Society and the West Virginia State Medical Association and is at present a member of the staff of the Ohio Valley General Hospital

GENERAL

Examinations in Ophthalmology—The American Board of Ophthalmology will conduct examinations in Philadelphia, June 8, and in New York, June 10 Applications must be filed at least sixty days before date of examination Address communications to Dr William H Wilder, 122 South Michigan Avenue, Chicago

Diploma Missing—Dr Morton J Goodman, Portland, reports that his diploma from the University of Oregon Medical School, issued in June 1929, has been lost The name on the document is either Morton J Goodman or Morton Jacob Goodman Dr Goodman's diploma for his bachelor's degree and his certificate of membership in Alpha Omega Alpha are also missing

Society News—Dr Robert L Payne, Norfolk, Va., was elected president of the Southern Surgical Association at its annual meeting at Sea Island, Ga., December 13 Drs William T Black, Memphis, Tenn., and William P Nicholson Jr, Atlanta, were elected vice presidents and Dr Edward W Alton Ochsner, New Orleans, secretary Next year's meeting will be in Hot Springs, Va.—The twelfth annual meeting of the American Orthopsychiatric Association will be held at the Hotel Pennsylvania New York, February 21-23, under the presidency of Dr George S Stevenson, New York.—The Central Neuropsychiatric Hospital Association will hold a special meeting in Chicago, January 25 This organization is made up of twenty eight sanatoriums in the middle states, Dr Douglas A Johnston, Cincinnati, is secretary

Seaboard Medical Association—Dr Archibald M Burfoot, Fentress, Va., was elected president of the Seaboard Medical Association at the annual meeting in Kinston, N.C., December 4-6, he succeeded Dr Paul F Whitaker, Kinston The 1935 session will be held in Old Point Comfort, Va. The program included a symposium on diseases of the kidney presented by Drs Coy C Carpenter, Wake Forest, N.C. Frederick C Rinker and Walter B Martin, Norfolk, Va., DeWitt Klutz, Washington, N.C., William B Kinlaw, Rocky Mount, Joseph R Latham, New Bern, and Manfred Call, Richmond Other speakers were Drs James C Masson, Rochester, Minn., on Use of Living Sutures in the Repair of the More Difficult Abdominal Hernias, Oscar L Miller, Charlotte, N.C., "Disability in the Lower Part of the Back," and Marvin Pierce Rucker, Richmond, "Obstetric Shock"

Branch Urologic Meeting—The first meeting of the recently created Southeastern Branch of the American Urological Association was held at the Biltmore Hotel, Atlanta, December 7-8 In addition to remarks on the importance of branch societies by Dr Gilbert J Thomas, Minneapolis, secretary, American Urological Association, the following program was presented

Dr Benjamin S Barringer New York Present Day Methods of Treating Cancer of the Prostate

Dr George R Livermore Memphis Pain in Cases of Dilated Pelvis and Ureter

Dr William E Lower Cleveland Problems of Lesions of the Right Upper Quadrant

Dr Robert H Herbst and Dr Carl Apfelbach Chicago Renal Hypoplasia

Dr Hugh Cabot Rochester Minn., Treatment of Undescended Testicle

Dr Howard S Jeck New York Nupercaine as a Spinal Anesthetic, with Special Reference to the Employment of Solutions of High Dilution

Dr Edwin Beer New York Historical Review of Bladder Tumors

Dr John R Caulk St Louis Bladder Neck Obstructions in Children

Dr William F Braasch Rochester Recent Advancements in the Treatment of Infections Involving the Urinary Tract

Dr William D Haggard, Nashville, acted as master of ceremonies at the dinner, Friday evening

CORRECTION

Distinction Between Science and Art—The quotation under this title at the bottom of page 1847 in THE JOURNAL, Dec 15, 1934, was written by the venerable Dr John Brown of Edinburgh, that fact was clearly stated by Dr George Blumer in his paper read before the William Harvey Society, but the quotation marks were inadvertently omitted in THE JOURNAL

The Dangers of Quack Medicines

In spite of repeated exposures and particularly the book on the Composition of Secret Remedies," published by the British Medical Association, the trade flourishes and even reputable journals are full of glaring advertisements of their extraordinary virtues. An important statement on the dangers that may result from this uncontrolled sale has therefore been prepared by the council of the Royal College of Surgeons at the request of the Standing Committee on Scientific Research of the Economic Advisory Council (a body appointed by the government). The council of the Royal College of Surgeons declares that the sale of secret remedies has reached large dimensions and that in the interests of the public it should be placed under some control. Among the objectionable features of the uncontrolled sale are mentioned the following: 1 The remedy may contain some drug that is injurious such as acetanilid (headache powder). 2 More generally the remedy is purely fraudulent, containing nothing of therapeutic value. 3 The claims made are always exaggerated and in general are purely fraudulent. The college points out that some form of control is exercised in many countries. In Germany a large group of preparations can be sold only under medical prescription and cannot be advertised. In France they can be sold only under government approval. In England there is no effective control either of the composition of secret remedies or of the claims made for them. In fact proprietary medicines are definitely excluded from the operation of the Food and Drugs Act.

Recalling that in 1914 a select committee (appointed by the government) advocated the giving of wide powers of control over both the sales and the claims made, to the ministry of health, the council expresses the opinion that the problem can be dealt with adequately only on these lines. Such control should ensure that the article is not injurious, that its description is not fraudulent, that the sale and methods of advertisement are not against the public interest and that no medicine or appliance is advertised as a cure for blindness, Bright's disease, cancer, consumption, diabetes, epilepsy, fits, locomotor ataxia, lupus or paralysis. A bill is at present being considered by the parliamentary committee on food and health the object of which is to prohibit the sale or advertisement of medicines or appliances for the cure of certain conditions, the use of fictitious testimonials and the offer of diagnosis or treatment by correspondence. The representatives of the "patent medicine" trade declined to support any bill on the lines of the select committee's report but it agreed not to oppose a measure such as has now been drafted.

The Health of the School Child

The annual report of the chief medical officer of the board of education for 1933 has just been published. During the year 3,000,000 children passed under definite medical review and subsequently 2,000,000 reinspections were carried out. Of the 1,855,499 children submitted to routine examination 20,579, or 1.1 per thousand were found to be malnourished and requiring treatment, and 23,760 or 1.28 per thousand, were found to be undernourished and requiring observation. The figure for 1932 of 'malnourished' children requiring treatment was 10.7 per thousand and for 1931 was 11.2. The massed return for 1933, compiled from figures submitted by 316 local education authorities indicated that the condition of the school

children throughout England and Wales in 1933 was similar to that in the two preceding years and showed no deterioration. The total number of meals provided in the year 1933-1934 was 68,800,000, an increase of 6,500,000 over 1932-1933, and the number of children who received meals was 414,800, as compared with 399,400 in 1932-1933.

Sir George Newman therefore concludes that the general health and nutrition of the population of England and Wales, taken as a whole was well maintained in 1933, in spite of economic and social difficulties, distressing as these have been. 'There can be no question,' he says, 'that the nutrition of the English people is better today than at any past period of which we have record. But that does not say or mean that present standards of health and nutrition cannot be or should not be improved.' It may be remembered that he came to a similar conclusion in his report on the health of the nation (*THE JOURNAL*, Nov. 3, 1934, p. 1388).

UNEMPLOYMENT AND SCHOOL LEAVING

Referring to the children who have left school (at the age of 14) Sir George Newman says that they have passed out of the reach of the medical services, the school meals and the physical training provided. They may be in need of some of these. 'A state which allows its young people to degenerate, physically or mentally, because of unemployment is incurring a grave responsibility. Perhaps of all the disadvantages of prolonged unemployment in youth the worst are the disappointment and demoralization which ensue on enforced idleness and the more or less complete wreck of aspirations.'

THE VALUE OF DANCING

Sir George Newman emphasizes the importance of dancing as a vital form of bodily exercise which deserves a place in physical education. He regards it as a mode of expressing emotion. 'Children naturally express their pleasure in song and dance, the desire for rhythmic movement is strong in them. More and more the conviction is growing that the combination of music and dance movement (as distinct from physical training) is not only a great art but a valuable means of educating the body, mind and character in one harmonious whole.'

Reform in Midwifery Practice

At a public health congress held in London, Prof. F. J. Browne, director of the obstetric unit at University College Hospital, complained of the lack of cooperation between the medical officers of municipal antenatal clinics and private physicians which meant a gap between diagnosis and treatment. Medical officers at the clinics are not allowed to give treatment, the patient must be referred to her own physician who is often too indifferent or too occupied to give her the treatment she requires. The time has come according to Professor Browne, to bridge this gap by taking midwifery out of the hands of the general practitioner and establishing a service of specialists, thoroughly trained in obstetrics, to work in cooperation with highly trained nurse-midwives. This team would be responsible for the care of the patient during pregnancy and delivery. The general practitioner, he says, is unsuited for the practice of midwifery for the following reasons: 1 Its practice calls for a long specialized training, impossible to give the undergraduate medical student. Nothing less than three years of postgraduate practice in a large maternity hospital will give the necessary skill. 2 In the course of his work the general practitioner is continually in contact with septic wounds and may have to go direct from such a case to a midwifery case, with grave risk of infecting his patient. 3 Midwifery practice is incompatible with the claims of general practice. It occurs at irregular times and interrupts the physician's work, entailing dangerous haste.

The high maternal death rate will be overcome only by a specialist service in which team work will replace the confusion of the present midwifery service

Farce of Opium Control

A series of articles in one of the Paris journals by Jean Perrigault shows how difficult it will be to prevent the use of opium by the Chinese, despite the prohibition of its importation. In 1927 the drug habit was prevalent not only all over China but also in the International Settlement and in the French concession of Shanghai, where a half clandestine, half tolerated, sale existed. In May 1934 not a single shop or resort existed in Shanghai where the drug could be obtained, but this did not mean that the 400,000 Chinese in the French concession or the 1,500,000 in the International Settlement could not secure as much as they wished, hence 50 per cent of these Chinese continue to smoke from ten to fifty pipes a day. If they cannot get opium in the International or French settlements where they reside, there is no restriction to buying all they want in the adjacent Chinese portion of Shanghai. The French police have raided the resorts in their concession repeatedly, but to no avail.

In old China an antiopium league has been founded, but this is only a subterfuge for the merchants who sell the drug under the name of "antiopium."

Chiang Kai Shek, who controls China at present has been converted to Protestantism. He is conscientious and able, but the taxes on opium are much needed by the other Chinese generals, hence the difficulty of controlling the sale.

These observations of Perrigault are verified by the report of the last meeting at Geneva of the Commission on Narcotics of the League of Nations. It was found that the volume of legalized commerce in opium and other narcotics continues to decrease progressively. On the other hand, and especially in countries where control is difficult, the quantity due to illegal manufacture is constantly increasing. The condition of affairs in China is getting worse, both as regards the smuggling and illegal importation as well as in the use of narcotics. It is hoped that a new process by which the various derivatives of opium could be obtained from the juice of the poppy without passing through the intermediate opium stage will enable a better control to be made. A report on this subject will be made at a future meeting of the commission.

Congress of Preventive Pediatrics

At the fourth session of the International Association of Preventive Pediatrics, at Lyons, September 27, two subjects were discussed: prophylaxis of malaria and prophylaxis of rickets and spasmophilia. The latter subject was presented in the form of reports by Monrad of Denmark and Rominger of Germany.

Monrad stated that rickets, which is rare in Denmark at present, had decreased in frequency even before the discovery of vitamin D. This was due to hygienic measures of various kinds, especially education of the mothers, all of whom are given instruction in hygiene. Heredity does not play an important part in the etiology. Congenital rickets is nonexistent. The osteoporosis found in premature infants is not due to rickets. In congenital craniotabes there is neither hypophosphatemia nor hypocalcemia. Rickets cannot be regarded as a form of avitaminosis. It is useless to give cod liver oil, viosterol or actinotherapy as a routine during pregnancy or to the new-born. Large doses of viosterol are not without their dangers. Tuberculosis and syphilis also cannot be considered as etiologic factors in rickets. The latter is the result of a

disturbance in the ratio of phosphorus to calcium. The best methods of prophylaxis are general hygiene and avoidance of slowly developing chronic intestinal infections, especially inability to digest fats. Spasmophilia is not frequent and also is a contraindication to the prescribing of viosterol, because it may disturb the phosphorus-calcium ratio.

Rominger, the second speaker, found that, despite some progress, rickets has not disappeared. He believed that prophylaxis is especially necessary in the case of premature infants and twins, in whom the calcium content of the blood and tissues is often deficient. Although rickets could no longer be regarded as hereditary, there is a certain predisposition to it. Breast-fed infants, especially at the period of weaning, must be carefully watched. He believed that the ultraviolet rays should be used during pregnancy, as early as the third month, for six weeks, three treatments a week of short duration. Irradiated foods have not given the results that were hoped for. Cod liver oil is subject to variations in composition and is not always given as regularly as could be wished for. The best prophylactic measure is to give viosterol in small doses, beginning with the fourth month. This is especially true in poor families, in which the nursing's nourishment is not easy to improve. Spasmophilia can be considered as a condition indicating cure of the rickets.

Seckel of Cologne, Germany, did not agree with the last statement, because, in two thirds of the cases of spasmophilia, roentgenography fails to show any evidence of cure of rickets.

Cathala of Paris stated that, in spite of the more common use of cod liver oil and viosterol, many cases of rickets are still seen in the Parisian hospitals.

Woringer of Strasbourg maintained that the best prophylactic measure was heliotherapy, but that pigmentation of the skin should be avoided.

Lesne of Paris has found that prolonged digestive disturbances and lack of sunlight are the principal causes. Inability to digest starchy foods plays a more important part as favoring rickets than that of fats. These digestive disturbances probably act by affecting either the assimilation of calcium or in increasing its elimination, with resultant calcium insufficiency.

A Paris Surgeon 103 Years Old

Three years ago the Academy of Paris celebrated its foundation in 1831, and at the same meeting the fiftieth year of membership of one of its fellows, Dr. Alexander Guénot. November 16 the doctor celebrated his 103d birthday, still mentally active and engaged in writing his memoirs. On this occasion he recalled having witnessed many of the stirring events in the history of France during the last ninety years. Dr. Guénot ascribes his longevity to daily walks, a regular mode of life and the fact that he massages his arms and legs twice a day.

Mortality Rate in France

The death rate during the past decade has been higher in France than in neighboring countries. In England it is 12.15 per thousand, in Switzerland 12.27, in Denmark 11.20 and in Holland 9, while that of France is 16.80. The climatic and social conditions not being any more unfavorable in France than in these other countries, one must conclude that hygiene is not as far developed here.

Every effort is being made to establish better hygienic conditions in rural districts. The majority of cities with a population of more than 5,000 now are equipped with sewerage, but there are many smaller centers where no such provision has been made. More than 295 cities, or one fourth of the total number in France, have no sewers. An effort is being made to correct this lamentable state of affairs.

The water supply of a number of cities has also been far from that which the hygienic standard of today demands. The

government has recently appropriated large sums to correct this. If one considers as cities the centers of population having more than 2,000 inhabitants, and if one excludes the department of the Seine, in which Paris is located, the mortality rate is above 10 per thousand. In rural communities, that is, those with less than 2,000 inhabitants, the rate is higher, 17.8 per thousand. This shows that much needs to be done in the rural districts in the form of sewerage, pure water supply and proper food. Sixty per cent of the population of France is engaged in agricultural work, hence the necessity of giving the farmer the benefits of better hygienic conditions.

The best form of preventive medicine and the least costly is hygiene, and this is especially applicable to rural communities.

ROME

Oct 30 1934

Discussion of Health Insurance

The second annual reunion of the Associazione Italiana di medicina legal was recently held at Montecatini. The medico-legal problems of insurance against disease were discussed. Dr. Bellucci, head physician of the Cassa Nazionale Malattie degli Addetti al Commercio, pointed out that the establishment of insurance against disease required the collaboration of jurists, economic-social resources and physicians. At present there are two tendencies in the field. First the administration of care and pecuniary aid to cover the most pressing necessities of life is required in favor of insured sick persons. By the second plan the insured are offered medical services. Between these two extremes there are intermediate stages. Many persons claim that the characteristic differentiation of insurable diseases is nearly impossible which is not the case if a definite interpretation is given to the two conceptions on incapacity and inability for work. Dr. Diez proposed that the inability to work be considered a disease from the point of view of insurance.

Dr. Cazzaniga spoke on chronic diseases from the point of view of insurance. In regard to professional secrecy in health insurance it was decided that the question presents different angles according to the different relations between physician and patient. The physician in charge of the treatment of a patient is bound to keep medical secrecy but not so the insurance physician. A new intermediate figure between the physician in charge of the case and the insurance physician is the consultant physician who acts also as an overseer and who at present is found in Italy only in some insurance societies.

Congress of Colonial Medicine

The fifth National Congress of Colonial Medicine was recently held at Naples under the chairmanship of Prof. Aldo Castellani. The first topic, hydromineral and physical treatments of tropical diseases, was presented by Dr. Castronuovo of the University of Naples. He reviewed the old traditions related to the African springs from the time of the Romans. He discussed the use of the sun bath, the light bath, electrotherapy, diathermy and roentgen therapy in several tropical diseases.

The second topic, blastomycosis, was presented by Dr. Castellani who classifies blastomycosis into two large groups, cutaneous and internal. Cutaneous blastomycosis can also involve the mucosae and the scalp. He makes the distinction of the principal types—pulmonary, hepatosplenomegalic and cerebrospinal—in the visceral forms. The pulmonary type can simulate pulmonary tuberculosis; the hepatosplenomegalic type might be mistaken for syphilis. Two subtypes are interesting in the cerebrospinal type: the blastomycetic meningitis, the symptoms of which resemble those of cerebrospinal meningitis and the blastomycetic cerebral abscess, which is characterized by the rich content of fungoid cells in the pus. The speaker suspects

the presence of blastomycosis especially in various cutaneous diseases of a pseudofurunculoid type, which are intractable to any treatment and which improve under antiblastomycotic treatment. The pathologic element that characterizes blastomycosis is the large granulomatous nodule. A microscopic examination shows large bright cells with large granules of protoplasm. To make a diagnosis it is necessary to take cultures. In clinical practice a general diagnosis is sufficient to start the treatment. Dr. Castellani discussed the differential diagnosis of blastomycosis, which in temperate climates concerns especially cutaneous verrucous tuberculosis. The decision is based on the biologic and microscopic examinations. In tropical countries there is a danger in mistaking blastomycosis for inguinal granuloma, frambesia and pyogenic dermatitis vegetans. The prognosis for the patient's life is grave in the cutaneous form of blastomycosis. Nevertheless, by early diagnosis and early treatment one often succeeds in saving the patient. Visceral blastomycosis is, as a rule, fatal. The therapeutic measures advised are many, and they are given either by the subcutaneous or by the internal route. The administration of large doses of potassium iodide, even from 20 to 30 Gm daily, is considered even today the best remedy. Dr. Di Guglielmo, clinical physician of Catania spoke on brucellosis. He reported the results of his use of intravenous vaccines by the administration of which he has secured satisfactory results in more than 300 cases. Dr. Caronia spoke also, on the value of intravenous vaccines in therapy of brucellosis.

Dr. Giordano gave a report of his experiments carried on with Dr. Nastasi on exanthematous fever in Tripolitana. He emphasized the role of dogs in the transmission of the disease and the constant negative results of the Weil-Felix test.

The congress, having in mind the growth of colonial medicine, voted for the creation of a chair of colonial pathology in Naples, the center of Italian colonial life.

New Surgical Society

The Società Italiana di Chirurgia Plastica e Riparatrice was recently founded in Rome near the surgical clinic of the University of Rome. Drs. Roberto Alessandri and Manna were appointed honorary and acting presidents, respectively. The first congress of the new society will meet in Rome during the seventh week of Lent, Easter week, 1935. The official topic, previously selected, is the History and Development of Plastic Surgery in Italy, with Dr. Manna as official speaker.

Meeting of Supreme Council of Public Health

The members of the Supreme Council of Public Health in Italy recently met at Rome under the chairmanship of Dr. Dante De Biasi, an Italian academician. Dr. Basile, general director of public health, spoke on the public health of the country. The health laws promulgated for the first time in 1888 have done much to improve the sanitary conditions of the country. The regulations of the last few years have resulted in a decrease in the rate of infant mortality, as shown by the figure of 123 per hundred for 1932. Syphilis, even now, is important as a cause of death during the first month of life. Because of this fact, the government provided last March for the establishment of centers for free treatment of syphilitic mothers and their infants. The second problem discussed was that of the campaign against malaria. The work of antituberculosis organizations was then estimated. The following data were compiled in 1933: total number of first consultations with examination, 261,216, including a total number of 7,229 tuberculous patients and 143,489 nontuberculous persons. The pulmonary and pleural localization of tuberculosis proved to be more frequent in women than in men. The members of the council also discussed the abolishment of, and restriction in, the use of diacetylmorphine and cocaine.

JAPAN

(From Our Regular Correspondent)

Oct 31, 1934

The International Red Cross Conference

The fifteenth international conference of the Red Cross was held in Tokyo, October 20-29. With the exception of one meeting in Washington, this international conference was the first to be held outside Europe, moreover, this was the first world conference that has ever been held in Japan. From fifty-seven countries among sixty-one member countries, 252 delegates were present. The sixty-one delegates from America and the Philippines formed the largest delegation, and next largest was the Japanese, consisting of thirty-six delegates.

The board of governors and the board of delegates discussed among others the following important matters at the final meeting, October 19: official acceptance by the Soviet Union of the invitation to membership in the League of the Red Cross Societies, acceptance of the financial report of the league, presented by Mr. Ernest J. Swift, and of the budget of 2,500,000 francs for the year 1935, election of Col. Guillaume Favre and Dr. J. Max Olano, as president and vice president, respectively, of the board of delegates, recommendation of the appointment of Prince Tokugawa as president of the fifteenth international conference, a proposal by Marquis Jose Valdez of Spain to name Madrid as the place of the sixteenth conference in 1938, appointment of Mr. Swift to make a summary of all national reports on Red Cross activities.

The financial report made by Mr. Swift showed a net income of 1,366,776.41 francs and a net expenditure of 1,322,009.51 francs, giving an excess of income of 44,776.90 francs for the first half of the year 1934. The estimated expenditure for the last half of 1934 was 1,300,079.06 francs. The proposed budget of 2,500,000 francs for the year 1935 was approved. This smaller budget for the coming year is due to the economy effected by moving the league headquarters.

THE OPENING CEREMONIES

In the presence of Prince Kotohiko Kanin and Premier Okada and other cabinet ministers, the opening session of the conference was held on the 20th in the headquarters of the Japan Red Cross Society and broadcast throughout the empire. Dr. Rene Sand, technical counselor of the league, acted as interpreter, rendering French and German into English, and English into French.

WORLD ACTIVITIES

On the 21st, Mr. Swift reviewed the work of the societies throughout the world during the last year.

The Indian Red Cross now gives special attention to the protection of mothers and children, popular health instruction, tuberculosis work and cooperation with hospitals. Its work for disaster victims has been placed on an organized basis.

The close cooperation of the Turkish society with the government is attested by the fact that its president is the minister of health and social work and that the secretary general of the Red Crescent is a high official of that department. The Red Crescent has been able recently to increase its resources through the sale of special stamps and the organization of a flower day.

The Australia Red Cross has worked mainly in the field of help to disabled ex-soldiers. It makes generous contributions to hospitals and to the public nursing services, which are of special value in territories where people live isolated and far from one another. Special attention has been given by the Junior Red Cross to sufferers from infantile paralysis.

Among the activities in the United States may be mentioned the teaching of first aid, life saving and home hygiene, work for the blind and for ex-soldiers, rural nursing and disaster relief. The number of volunteers enrolled is 70,000 and with

their help the Red Cross has carried on a stupendous piece of work, distributing among those who needed help 18 million bushels of wheat and 844,000 bales of cotton. The operating cost of this immense operation amounted to less than 1 per cent of the value of the goods contributed. The distribution has lasted seventeen months.

In the Philippine Islands the Junior Red Cross during the single year 1933 provided dentistry facilities for 660,000 children. The Red Cross has taken over new responsibilities in connection with lepers.

The Canadian Red Cross is engaged in a unique activity in the form of the seaport nurseries conducted since 1920 and its system of outpost hospitals, which is now considered to have passed the experimental stage. It has this year begun the first aid work on highways, and the number of registered nurses on its rolls for emergency service now number almost 1,000.

In Paraguay the Red Cross has 152 local committees, a membership of more than 16,000 and an annual budget of four million pesos. Besides the relief work, it has undertaken with the help of the Rockefeller Foundation a highly successful campaign against the hookworm.

Of special interest in Great Britain are the information services for hospitals, the hospital library, blood transfusion services, three orthopedic clinics and the rheumatism clinic of the British Red Cross. Its ambulance services include more than 350 vehicles. It supplies first aid detachments to meet the requirements of public meetings and of persons engaged on seasonal work, such as hop picking and herring fishing. It has taken the first step in connection with the air ambulances.

The Norwegian Red Cross maintains a large hospital and a sanatorium. During the last four years, two new hospitals and six new cottage hospitals have been established in addition to the maternity homes and homes for retired nurses. Nurses' training is provided from six different centers. It takes special interest in the health and welfare of seamen in the hospital ship *Viking*.

In Sweden 175 new sections have been established and 35,000 new members enrolled. Its membership represents 2 per cent of the population of the country. It has provided dental treatment for 8,000 school children and meals for 17,000. It maintains 200 ambulances and an air ambulance service.

In Germany it has a membership of 1,360,000, including 267,000 persons trained and organized in first aid detachments. In 1933, assistance was given in more than two million cases. It has 10,000 nurses working in 427 Red Cross institutes of various kinds providing beds for 20,000 patients. It further maintains 2,300 dispensaries, 2,000 creches, day nurseries, kindergartens and soup kitchens.

Cooperation between the Red Cross and the government is provided for in Belgium in the statutes of the national Red Cross Society. Its progress since 1930 is reflected in the ever growing success of the yearly Red Cross Week, which is a national event. Other features are the opening of a second health center, the organization of 500 first aid posts on highways, and an agreement entered into with the railway administration and the shipping authorities to provide for the rapid intervention of the Red Cross in railway and shipping accidents.

The three societies constituting the French Red Cross are performing valuable service in the training of nurses, including the training of nurses for air ambulance work.

Under the direction of an energetic central committee and with the cooperation of numerous local committees, the number of hospital sanatoriums, dispensaries, first aid posts and ambulances in Spain is rapidly increasing. The number of cases handled in the dispensaries is 140,000.

The most modern technic has been introduced in the Italian Red Cross sanatoriums, surgical and orthopedic institutions, preventoriums, malaria stations, school medical services, first aid

posts and motor ambulance services. More than two million home visits are made by visiting nurses each year.

The Red Cross in Hungary employs sixty-two social workers, who have received ten months' special training. Four night shelters have been established and seventy-four homes for the aged.

The principal activities of the society in Austria are first aid, tuberculosis work and maintenance of the dispensaries. Special attention has been given to helping mothers in childbirth and to assisting poor children.

Among the society's activities in Yugoslavia are the nurses' training school and the orphanages and treatment stations. The Junior Red Cross now extends to a very large proportion of the entire school population.

In Czechoslovakia the Red Cross conducts more than 400 institutions of various kinds, including a social service school, a shelter for emigrants, a night shelter at Prague, a club for apprentices, children's homes and health centers. It is associated with the health demonstration called *Vrsovice*.

In Latvia the society derives part of its income from lotteries and from the sale of playing cards. It maintains the Riga Hygiene Museum. It conducts seven sanatoriums, fifty-eight health centers, two nursing schools, a workroom for the manufacture of artificial limbs, a motor ambulance service and a medical supply depot.

In the Soviet Union the Red Cross has five and a half million members. "The Young Friends of the Red Cross," divided into 88,000 groups, comprise 900,000 children between 10 and 16 years of age. The budget for 1934 reaches the imposing total of 145 million rubles. The constituent societies making up the alliance maintain 145 hospitals, 1,000 polyclinics, eighty-five sanatoriums and rest homes, 700 disinfection stations, 200 pharmacies, 500 depots of medical material, 80,000 health posts in industrial institutions, and 100,000 village health centers.

FINAL ACTIVITIES

October 23, it was announced that the empress of Japan had donated 100,000 yen to the international Red Cross committee. The conference practically closed on the 26th, leaving the 27th and 28th for pleasure excursions. The city of Madrid was selected for the sixteenth conference, which will be held in the fall of 1938.

RIO DE JANEIRO

(From Our Regular Correspondent)

Nov 15, 1934

Alterations of the P Wave of the Electrocardiogram

Drs Dante Pazzanes and Roberto Pires of Campos recently presented before the Associação Paulista de Medicina a study of the P wave based on 1,507 electrocardiograms made on 1,105 patients. The speakers reached the following conclusions: A P wave that either lasts more than 0.1 second or is more than 2 mm high in any lead is abnormal. The most frequent abnormality of the auricular wave is its lengthening. Abnormal P waves were found in ninety cases: forty-one in mitral stenosis, thirty-seven in myocarditis, ten in aortic insufficiency, one in asthma and one in tuberculosis. The P wave was normal in 52 per cent of cases of mitral stenosis, it was within normal limits, although slightly altered, in 20 per cent of the cases and there was fibrillation in 28 per cent of the cases. The changes of the P wave can serve as a basis for the prognosis in cases presenting mitral stenosis. An inversion of the P wave in the first lead was found only in a case of situs inversus and in the second lead in three cases of myocarditis. Abnormalities of the P wave are rather frequent in myocarditis. Aortic insufficiency was the cause of the lengthening of the P wave in 10 per cent of the cases. Also other causes were observed less frequently.

Sulphopyretotherapy in Dementia Paralytica

Dr Mario Yahn of São Paulo in a recently published article on sulphopyretotherapy in dementia paralytica reached the following conclusions: Deep intramuscular injections of 3, 10 or 12 cc of an 8 per thousand sulphur solution in oil causes an elevation of the temperature to 104 or 104.9 F. There is a certain relation between the intensity of the local inflammatory phenomena and the rise of the temperature. When the temperature is very high it is associated with chills, labial herpes, intense perspiration, nausea and vomiting. The only inconvenience of sulphur injections is the intense local pain they cause. They are well tolerated by patients suffering with arteriosclerosis, torticollis or hemiplegia as well as by old persons. Sulphopyretotherapy provokes a psychic remission with improvement of the patient's general condition, and gain in weight. In two cases it retarded the appearance of epileptiform attacks. Response to the treatment was observed in 45.5 per cent of the cases, with 22.7 per cent very good remissions and 9.2 per cent of good remissions and 13.6 per cent of fair remissions in the group of patients with the expansive and megalomaniac forms. The remaining 54.5 per cent of the cases included stationary cases and one fatal case. The mental and general condition of this patient was bad and death followed six days after the first series of injections. The cerebrospinal fluid was in general favorably modified by sulphopyretotherapy. The typical features of dementia paralytica in the curve of the colloidal benzoin test not infrequently were lost or at least attenuated. The Wassermann test in the cerebrospinal fluid became less intense after the treatment, but negative results were never obtained. The Wassermann test in the blood did not change except in one case, in which it gave negative results before the treatment and positive results after it. The first injections seemed to activate the syphilis.

A New Polyclinic

A new polyclinic, organized by the board of directors of the Faculdade Fluminense de Medicina with the aid of the government of Rio, was recently inaugurated at Nictheroy, capital of the state, for the care of the poor. The four-story building on a suitable site, has ample equipment for diathermy and for ultraviolet and roentgen therapy. The library occupies the entire fourth floor. All the wards are large, with modern equipment of the best type. The polyclinic is divided into the following departments, each of which has its own head and personnel: medical and surgical clinics, obstetrics, gynecology, ophthalmology, otorhinolaryngology, medical and surgical pediatrics and orthopedics, urology, neurology and psychiatrics, dermatology and syphilology, tropical diseases, phthisiology and odontology. There are two amphitheaters, each accommodating 244 persons, projection apparatus and a speaking platform.

Marriages

CHARLES THEODORE HAZZARD to Miss Blim Appell, both of Mount Vernon, N. Y., Dec. 21, 1934.

REUBEN H. MINARS, New York, to Miss Regina Schoolnik of Belle Harbor, N. Y., Oct. 27, 1934.

SAMUEL LOUIS GOLDBERG, Chicago, to Miss Gertrude Beatrice Marks of Detroit, Dec. 24, 1934.

JAMES E. P. DAVIA to Miss Elsie I. Crabtree, both of Chicago, June 16, 1934.

WALLACE P. RITCHIE to Miss Alice R. Otis, both of St. Paul, recently.

CORRECTION

Not Married—The marriage announcement that appeared in THE JOURNAL, Dec. 22, 1934, of Dr. Leslie H. Remers of Chicago to Miss Margie Ebaugh of Akron, Ohio, was erroneous.

Deaths

Gotthelf Carl Huber, since 1914 professor of anatomy and director of the anatomic laboratories, University of Michigan Medical School, Ann Arbor, and since 1927 dean of the graduate school, died, Dec. 26, 1934, in the University Hospital, aged 69. Dr. Huber was born in Hoobly, India, Aug. 30, 1865. He received his medical degree from the University of Michigan Department of Medicine and Surgery, Ann Arbor, in 1887, and later studied in Berlin and Prague. Before 1914 he had served as assistant demonstrator of anatomy, instructor, assistant professor of histology, junior professor of anatomy and professor of histology and embryology and director of the histologic laboratory at his alma mater. For many years he was also professor of histology and embryology at the University of Michigan Homeopathic Medical School and for one year, 1911 to 1912, professor of embryology at the Wistar Institute of Anatomy in Philadelphia. He was a member, past president, secretary and treasurer of the American Association of Anatomists, and a member of the American Association of Pathologists and Bacteriologists and the American Philosophical Society. Dr. Huber was the official reporter of the section on anatomy at the seventeenth International Congress of Medicine in London and was chairman of the medical fellowship board of the National Research Council. During the World War, as a contract surgeon, he carried on extensive investigations on the repair of severed peripheral nerves for the Surgeon General's Office, U. S. Army. For many years Dr. Huber was associate editor of the *American Journal of Anatomy* and managing editor of the *Anatomical Record*. He was the author of textbooks of histology and the editor of "Piersol's Human Anatomy."

John Montgomery Baldy, Devon, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1884, member of the House of Delegates in 1914 and fourth Vice President of the American Medical Association in 1918, past president of the bureau of medical education and licensure, formerly professor of gynecology, University of Pennsylvania Graduate School of Medicine, first commissioner of welfare of Pennsylvania, at various times served on the staffs of the Pennsylvania Hospital, Jewish Hospital, Frederick Douglass Memorial Hospital and St. Agnes' Hospital, Philadelphia, fellow of the American College of Surgeons, aged 74, died, Dec. 13, 1934, of a self-inflicted bullet wound.

Sydney Kuh * Chicago, Universität Heidelberg Medizinische Fakultät, Heidelberg, Baden, Germany, 1890, clinical professor of psychiatry, Rush Medical College, member of the American Neurological Association, past president of the Chicago Neurological Society, senior attending neurologist to the Michael Reese Hospital, attending alienist and chief of staff, Cook County Psychopathic Hospital, consulting alienist, Chicago Lyng-in Hospital, formerly attending alienist to the Scieyth Hospital, now known as the House of Correction Hospital, aged 68, died, Dec. 27, 1934, of coronary thrombosis.

Edson Lowell Bridges * Omaha, Omaha Medical College, 1896, professor emeritus of medicine, University of Nebraska College of Medicine, past president of the Omaha Midwest Clinical Society, served during the World War, on the staff of the Nebraska Methodist Hospital and Deaconess Home, aged 60, died, Dec. 4, 1934, in Honolulu, Hawaii, of cerebral hemorrhage and pneumonia.

Samuel Herman Lippitt * Milwaukee, George Washington University School of Medicine, Washington, D. C., 1915, associate clinical professor of pediatrics, Marquette University School of Medicine, for many years on the staffs of the Mount Sinai Hospital and the Johnstown Emergency Hospital, aged 48, died suddenly, Dec. 7, 1934, of myocarditis.

Arthur Clark Dean * East St. Louis, Ill., Jefferson Medical College of Philadelphia, 1917, member of the South Dakota State Medical Association and the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, served during the World War, aged 47, died, Dec. 1, 1934, in St. Mary's Hospital.

John Johnston Singer, Greensburg, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1902, member of the Medical Society of the State of Pennsylvania, the American Roentgen Ray Society and the Radiological Society of North America, on the staff of the Westmoreland Hospital, aged 55, died, Nov. 30, 1934.

Mason Hamilton Brawley * Salisbury, N. C., North Carolina Medical College, Charlotte, 1910, past president of the Rowan County Medical Society, served during the World War, aged 51, on the staff of the Rowan General Hospital where he

died, Nov. 26, 1934, of internal injuries received in a fall down an elevator shaft.

John Hendren Bell * Staunton, Va., University of the South Medical Department, Sewanee, Tenn., 1909, member of the American Psychiatric Association, served during the World War, formerly superintendent of the State Colony for Epileptics and Feeble-minded, aged 51, died, Dec. 9, 1934, of coronary thrombosis.

Hiram Davis Lawhead, Woodland, Calif., Cooper Medical College, San Francisco, 1883, member of the California Medical Association, past president of the Yolo-Colusa-Glenn Society for Medical Improvement, formerly on the staff of the Woodland Clinic Hospital, aged 82, died, Nov. 29, 1934, of coronary occlusion.

Gordon Moncrieff Dean, Baltimore, University of Aberdeen Faculty of Medicine, Scotland, 1927, instructor in urology, Johns Hopkins University School of Medicine, formerly resident urologist at the Johns Hopkins Hospital, aged 34, died, Dec. 16, 1934, in Fort Lauderdale, Fla., of brain abscess.

Chauncey Eugene Tennant * Chehalis, Wash., Denver College of Medicine, 1894, Denver Homeopathic Medical College, 1897, member of the Colorado State Medical Society, member of the Western Surgical Association, fellow of the American College of Surgeons, aged 65, died, Nov. 14, 1934.

Arthur Foote Kilbourne * Rochester, Minn., University of the City of New York Medical Department, 1883, member of the American Psychiatric Association, aged 76, for forty-five years superintendent of the Rochester State Hospital, where he died, Nov. 30, 1934, of carcinoma of the gallbladder.

Enoch T. Dunaway, Amarillo, Texas, University of Louisville (Ky.) School of Medicine, 1893, member of the State Medical Association of Texas, on the staffs of the Northwest Texas Hospital and St. Anthony's Hospital, aged 74, died, Nov. 26, 1934, following an operation for appendicitis.

William Munson Goodwin * Newark, N. J., College of Physicians and Surgeons, Medical Department of Columbia College, 1894, on the staffs of St. Michael's Hospital and the Hospital of St. Barnabas and for Women and Children, aged 64, died, Nov. 21, 1934, of coronary thrombosis.

Lemar Munger Andrews * Warsaw, N. Y., Cleveland University of Medicine and Surgery, 1896, past president and secretary of the Wyoming County Medical Society, on the staff of the Wyoming County Community Hospital, aged 63, died, Oct. 1, 1934, of coronary occlusion.

Stephen D'Irsay, Paris, France, Medical Faculty of the Hungarian Royal University of Sciences Pázmány Peter, Budapest, 1917, formerly associate in the history of medicine, Johns Hopkins University School of Medicine, died, Dec. 1, 1934, in the American Hospital.

Lyman T. Reber, St. Louis, Beaumont Hospital Medical College, St. Louis, 1889, formerly connected with the city health department, aged 74, died, Nov. 15, 1934, of shock and hemorrhage as the result of lacerations of the wrists, self-inflicted, and iodine poisoning.

Watson Frederick La Rue Rodemann, Newark, N. J., Long Island College Hospital, Brooklyn, 1908, also a pharmacist, served during the World War, commissioner of registration for the county of Essex, aged 57, died suddenly, Nov. 16, 1934, of coronary thrombosis.

Marion Josephine Alexander * Louisville, Ky., University of Louisville School of Medicine, 1928, on the staff of the J. N. Norton Memorial Infirmary, clinical assistant in medicine at her alma mater, aged 38, died, Nov. 19, 1934, of acute dilatation of the heart.

Duncan Neil MacLennan, Toronto, Ont., Canada, M. R. C. S., England, and L. R. C. P., London, England, 1896, formerly assistant professor of ophthalmology, University of Toronto Faculty of Medicine, fellow of the American College of Surgeons, died, Oct. 19, 1934.

Frank Alfred Ireton, Bethel, Ohio, Medical College of Ohio, Cincinnati, 1906, formerly member of the school board of Bethel and Newtonsville, county health officer, 1919-1928, aged 55, died, Nov. 17, 1934, in the Bethesda Hospital, Cincinnati, of tuberculosis.

Royal Oscar Brown, Mount Morris, Ill., Rush Medical College, Chicago, 1903, member of the Illinois State Medical Society, president of the Ogle County Medical Society, aged 60, died, Dec. 15, 1934, in the Deaconess Hospital, Freeport, of coronary thrombosis.

Ebenezer Knox Smith, Duluth, Minn., McGill University Faculty of Medicine Montreal, Que., Canada, 1923, member of

the Minnesota State Medical Association, aged 64, died, Oct 4 1934, in the Rochester (Minn.) State Hospital, of hypertension and cerebral infarct

James William Henson @ Richmond, Va., Medical College of Virginia, Richmond, 1889, formerly associate professor of surgery at his alma mater, fellow of the American College of Surgeons, on the staff of the Retreat for the Sick, aged 71, died, Nov 28, 1934

George William Kimball, Coulterville, Ill., National Medical University, Chicago, 1896, also a dentist and druggist, formerly village president and president of the board of education, aged 66, died, Nov 19, 1934, of chronic interstitial nephritis

Alberic Hyacinthe Bellerose @ Rutland, Vt., School of Medicine and Surgery of Montreal, Que., Canada, 1892, past president of the Rutland County Medical Society, on the staff of the Rutland Hospital, aged 68, died, Dec 11, 1934, of heart disease

Emily G. Whitten Auge @ Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia, 1894, fellow of the American College of Surgeons, on the staff of the Woman's Hospital, aged 57, died, Dec 11, 1934, of heart disease

Stephen Tyler Parsons, Denver, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904, aged 74, died, Nov 15, 1934, in St. Luke's Hospital of bilateral pyonephrosis and diabetes mellitus

Charles Hopkins Rolston, Mount Clinton, Va., University of Virginia Department of Medicine, Charlottesville, 1884, for eight years member of the state legislature, aged 73, died recently, of injuries received in an automobile accident

George Russell King, Ann Arbor, Mich., University of Michigan Medical School, Ann Arbor, 1933, assistant resident neurologist to the University of Michigan Hospital, aged 26, was killed, Nov 23, 1934, in an automobile accident

Herman Trost Baldwin @ Newton, Mass., Harvard University Medical School, Boston, 1895, member of the New England Pediatric Society, on the staff of the Newton Hospital, aged 66, died, Nov 25, 1934, in Orlando, Fla.

Robert Bruce Meyer, Ann Arbor, Mich., University of Michigan Medical School, Ann Arbor, 1933, resident dermatologist to the University of Michigan Hospital, aged 26, was killed Nov 23, 1934, in an automobile accident

John Joseph McCabe @ Holyoke, Mass., University of the City of New York Medical Department, 1893, on the staff of the Holyoke Hospital, aged 61, died, Nov 13, 1934, of sarcoma of the neck and arthritis of the spine

Roy Gilbert Strong, Medina, Ohio, University of Buffalo School of Medicine, 1901, member of the Ohio State Medical Association, served during the World War, aged 56, was found dead, Dec 12, 1934, of angina pectoris

Robert Milligan, Ann Arbor, Mich., University of Michigan Medical School, Ann Arbor, 1929, formerly instructor in neurology at his alma mater, aged 30, was found dead, Nov 28, 1934, of a self-inflicted bullet wound

George C. Wingate, Charlotte, N. C., North Carolina Medical College, Charlotte, 1914, member of the Medical Society of the State of North Carolina, aged 52, died, Nov 19, 1934, in the Presbyterian Hospital

Herman Albert Voigt, Baltimore, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1927, aged 31, died, Nov 12, 1934, in the Mercy Hospital, of bronchopneumonia

Norman Lucca Drake, Little Falls, N. Y., University of the City of New York Medical Department, 1891, member of the Medical Society of the State of New York, aged 64, died, Dec 2, 1934, of angina pectoris

William Robert Cate, Commerce, Texas, Epworth College of Medicine, Oklahoma City, 1909, member of the State Medical Association of Texas, health officer, aged 64, died suddenly, Oct 18, 1934, of heart disease

Ernest D. Davis, Standardsville, Va., Medical College of Virginia, Richmond, 1889, member of the Medical Society of Virginia, aged 67, died, Dec 3, 1934, in the University of Virginia Hospital, University

Roderick Edwin Albright @ Allentown, Pa., Jefferson Medical College of Philadelphia, 1896, on the staffs of the Sacred Heart and Allentown hospitals, aged 62, died, Nov 23, 1934, of myocarditis

Lindsey William Scott, Willard, Ohio, Eclectic Medical College, Cincinnati 1929, aged 41, on the staff of the Willard Municipal Hospital, where he died, Nov 19, 1934, of splenectomy and hemorrhage

Edgar Sharon Turner, La Follette, Tenn., Lincoln Memorial University Medical Department, Knoxville, 1912, served during the World War, aged 50, died, Nov 18, 1934, of lobar pneumonia

George Glasgo Turfley, Pittsburgh, Cleveland Medical College 1879, member of the Medical Society of the State of Pennsylvania, aged 79, died, Nov 17, 1934, of bronchopneumonia

John Mays Clarke, Redondo Beach, Calif., California Eclectic Medical College, Los Angeles, 1915, formerly mayor of Redondo Beach, aged 67, died, Nov 24, 1934, of heart disease

Ambrose Chandler Bramlett, Oxford, Miss., Hospital College of Medicine, Louisville, Ky., 1887, part owner of a hospital bearing his name, aged 83, died, Dec 7, 1934, of heart disease

Patrick H. Casey, Baltimore, University College of Medicine, Richmond, 1900, aged 58, died in November 1934 at the Georgetown Hospital, Washington, D. C., of cerebral hemorrhage

Henry Snow Morris, Nashville, Tenn., Vanderbilt University School of Medicine, Nashville, 1890, aged 67, died, Nov 17, 1934, of arteriosclerosis and cerebral hemorrhage

Albert Stealy, Charlotte, Mich., Toledo (Ohio) Medical College, 1896, aged 72, died, Nov 5, 1934, in the Carney-Wilcox Hospital, Alma, of cerebral hemorrhage

John Herrington Beynon, Napanoch, N. Y., College of Physicians and Surgeons, Baltimore, 1888, aged 68, died, Oct 20, 1934, in New Orleans, of heart disease

Samuel Mowbrey Hammond, St. Petersburg, Fla., Yale University School of Medicine, New Haven, 1896, aged 64, died Nov 20, 1934, of coronary thrombosis

Walter Scott Sims, Jackson, Miss., Medical College of Alabama, Mobile, 1881, on the staff of the Jackson Infirmary, aged 80, died, Nov 24, 1934, of pneumonia

Franz Grossman, Waterbury, Conn., Independent Medical College, Chicago, 1897, aged 82, died, Oct. 10, 1934, of fracture of the right femur and pneumonia

Heath Ashby Dalton, Hillsville, Va., Medical College of Virginia, Richmond, 1914, aged 45, died, Dec 2, 1934, in a hospital at Staunton, of heart disease

Charles L. Steel, Three Forks, Mont., University of Maryland School of Medicine, Baltimore, 1882, aged 74, died recently, of cerebral hemorrhage

Sidney Prentice Phelps, Malone, N. Y., University of Vermont College of Medicine, Burlington, 1898, aged 61, died, Nov 17, 1934, of heart disease

Charles Lee Bond, Hartsfield, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1890, aged 68, died in November, of pneumonia

John Albert Sturges, Murrieta, Calif., Rush Medical College, Chicago, 1876, also a druggist, aged 84, died, Nov 23, 1934, of heart disease

John Mack Darden, St. Louis, Barnes Medical College, St. Louis, 1904, formerly police surgeon, aged 53, died, Nov 15, 1934, of heart disease

Edward Green Sewell, Bunkie, La., University of Louisville (Ky.) School of Medicine, 1895, aged 67, died, Oct 13, 1934, of angina pectoris

Job D. Orahood, Indianapolis, Medical College of Indiana, Indianapolis, 1884, formerly a druggist, aged 79, died, Nov 18, 1934, of myocarditis

Isaac Daniel Alger, Minneapolis, Harvard University Medical School, Boston, 1864, aged 90, died, Nov 9, 1934, of bronchopneumonia

Carey Allen Burke, Los Angeles, Ohio Medical University, Columbus, 1895, aged 65, died, Oct. 7, 1934, of cerebral hemorrhage

Andrew J. Bowen, Portal, Ga., Baltimore University School of Medicine, 1904, aged 55, died recently, of angina pectoris

Marcus L. Clark, Lynnville, Tenn., Vanderbilt University School of Medicine, Nashville, 1879, died, Dec. 2, 1934, of heart disease

Oliver M. Heilig, Millcreek, Ill., Barnes Medical College, Chicago, 1895, aged 65, died, Nov 23, 1934, of carcinoma

J. T. Tichenor, Waterford, Ky., Louisville Medical College, 1893, aged 64, died, Nov 17, 1934, of heart disease

Correspondence

TOTAL ABLATION OF THE THYROID

To the Editor—For a long time I have been interested in the relationship between thyroid activity on the one hand and cardiac insufficiency and angina pectoris on the other, and in discussions of patients at the Peter Bent Brigham Hospital and in published papers I have stressed the idea that myxedema was the acme of what is sought in cardiac therapy, namely, rest with incident decrease of cardiac work. A note of mine on a patient in the winter of 1925 states

A most interesting feature of this patient was the play between her chronic myocarditis and angina pectoris on the one side and her myxedema on the other. In the negative state of myxedema she had relatively few cardiac symptoms.

In another place I have written

It is true that with an existing cardiac lesion which may be either coincidental or caused by thyroid hypofunction, the decreased activity of so many body functions so happens in myxedema serves as a conservative force so far as the circulation is concerned. To put it another way the damaged heart has less work to do so long as thyroid activity is considerably below a normal level [*Rhode Island M. J.* 8:109 (July) 1925]. A lowered metabolic activity from thyroid deficiency may be a conservative process or form of cardiac rest that is advantageous to the heart [*ibid.*]

Still elsewhere has appeared

Were there not discomforts associated with myxedema on induced myxedema might be considered an ideal measure for the treatment of angina pectoris for the myxedematous patient actually by reason of the myxedema deposits himself much as we advise for the patient with angina pectoris [Christian, H. A. *Monographs on Diagnosis and Treatment Heart Disease*, New York, Oxford University Press 3:279, 1928.]

With this background I have welcomed the brilliant initiative of Drs. Blumgart and Berlin at the Beth Israel Hospital, Boston, and of Drs. Levine and Cutler at the Peter Bent Brigham Hospital, where my own clinic is, which has demonstrated that an artificially induced myxedema will have the same conservative influence on cardiac insufficiency and angina pectoris as had been observed and noted in natural myxedema.

It is well, too, to emphasize that natural myxedema is a disease which among other disturbances has been observed to be accompanied by evidences of myocardial insufficiency and coronary sclerosis with angina pectoris easily activated by too large a dose of thyroid, and so it behooves those in charge of cardiac patients with induced myxedema to be ever cautious to maintain those patients between the Scylla of the effects of cardiac overactivity and the Charybdis of the very real discomforts and disabilities of myxedema, a thing found to be very difficult of accomplishment in natural myxedema and already observed not to be easy in induced myxedema in patients with cardiac insufficiency or angina pectoris.

These several factors enter into the treatment of hypothyroidism with cardiac disturbances to render it a most fascinating problem in therapeutics and one which requires good clinical judgment and keen diagnostic ability to solve whether we are dealing with the problem of angina pectoris in the myxedematous patient, a coincident cardiac insufficiency in myxedema or a true myxedema heart [Christian, H. A. *Monographs on Diagnosis and Treatment Heart Disease*, New York, Oxford University Press 3:283, 1929].

I feel very sure that the care of those cardiac patients with artificially induced myxedema will require no less skill in their management. It is to be remembered that some of the disability of myxedema may require much time for its full development, sufficient time may not, as yet, have elapsed for the patients in whom myxedema has been induced to develop the full effects of the thyroid deficiency, a deficiency that can be replaced only in part by thyroid feeding, since the cardiac disturbance, which has led to the complete surgical removal of thyroid tissue, inevitably will hamper full restitution to a normal level. At best these cardiac patients will have more or less myxedema, if considerable myxedema must exist, then the patient may develop anemia or accumulations of fluid in

serous cavities, or more coronary arteriosclerosis, all of which are seen in natural myxedema and which in themselves burden cardiac function. It is only fair to assume that they may develop such disturbing factors and that these things will limit the applicability and the effectiveness of this new method of treating cardiac disease to a relatively small group of patients. Removing thyroid tissue has no known influence on the pathologic changes in the heart, which have been the fundamental cause of cardiac disability, by nature they are progressive, another hampering influence to the therapeutic effectiveness of thyroid ablation in cardiac disability. All of this must be taken into account in evaluating total ablation of the thyroid in the treatment of cardiac decompensation and of angina pectoris.

HENRY A. CHRISTIAN, M.D., Boston.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

DIAGNOSIS OF CHOLECYSTITIS

To the Editor—A white married woman, aged 26, complains of nausea and vomiting. The attacks recur about every month or six weeks or oftener if she eats meats and fatty or acid foods. She has burning pain in the epigastrium but does not have the severe pain of gallstone colic or an acute pancreatitis. She is free from symptoms between attacks, does her own housework and feels good. She has learned to live on a bland diet consisting largely of bread and milk. She has one living child 5 years of age who has gastro-intestinal attacks followed by a pale yellowishness of the skin which clears up in one or two days. One other child born nine years ago died at six weeks, cause unknown. She had a bilateral salpingectomy and appendectomy four years ago. She has been treated occasionally for anemia for the last five years and the present complaint dates back one year. She is 5 feet 3 inches (160 cm.) tall and weighs 130 pounds (59 kg.). She appears well nourished and there has been no loss of weight. The skin is a pale lemon yellow and the conjunctiva is slightly tinted. The head and chest are essentially normal and there are no heart murmurs. The liver is palpable about one fingerbreadth below the costal margin and is slightly tender over the gallbladder region. There is considerable tenderness in the epigastrium in the midline. The spleen is palpable but not tender about two fingerbreadths below the costal border and smooth. There is a midline scar below the umbilicus. The physical examination is normal otherwise. The Wassermann and Kahn tests are negative and no malarial parasites have been found. The blood count shows 2,600,000 red blood cells with 55 per cent hemoglobin. There is much anisocytosis, hardly any two cells the same size but no poikilocytes or nucleated reds. The white count shows 8,000 cells with 63 per cent polymorphonuclears, 30 per cent small lymphocytes, 4 per cent large lymphocytes, 2 per cent transitionals and 1 per cent eosinophils. Gastric analysis shows 43 points of free hydrochloric acid and 60 points of total acids. On account of the mild jaundice it was thought best to do a gastro-intestinal study instead of a cholecystography. The stomach is rather low for the amount of fat the patient apparently has in the abdomen. The stomach is cow horn shaped, of normal size with no filling defects or notches and did not show any peristalsis while being observed under the fluoroscope. It is freely movable and by palpation a normal duodenal cap was observed but the progress through the duodenum and first part of the jejunum was slower than the average. At this time a shadow appeared in the region of the gallbladder which filled with barium sulphate. It was also present on the films. It is about twice as dense as the average cholecystogram in a normal gallbladder and no stones were visible. The stomach was completely empty in five hours and the head of the meal had reached the transverse colon but the gallbladder shadow remained. However the gallbladder shadow had disappeared by the next morning. I should like to ask as to the most probable diagnosis and the proper management and treatment in such a case. I have considered cholecystitis, chronic hemolytic jaundice and pernicious anemia but the latter two are not consistent with the high hydrochloric acid. Neither can I think that a cholecystitis with or without stones could give rise to an anemia of this grade. If the anemia can be improved would it do the patient any good to remove that gallbladder? Please omit name. M. D. MISSOURI.

ANSWER—The symptoms enumerated are quite compatible with chronic cholecystitis with or without stones or hemolytic icterus. As expressed in the question, pernicious anemia must be considered because of the high grade anemia and high color index. However, the presence of free hydrochloric acid speaks against it even though sporadic reports of pernicious anemia with free gastric acidity have appeared in the literature. The digestive disturbances can well fit in with calculous cholecystitis even in the absence of colic. A cholecystogram revealing either a nonfilling gallbladder or negative shadows will be of considerable value. The large shadow resembling a gallbladder, obtained with a barium meal, may be a diverticulum of the duodenum.

due to traction by adhesions between the gallbladder and the duodenum or a congenital diverticulum in the third portion of the duodenum, a favorite location. The interesting facts in the relation of the symptoms are the peculiar yellow tint slight liver enlargement although the size of the liver is within normal range, and the definite splenic enlargement. It is necessary for proof to do a fragility test on the red blood corpuscles. If there is increased fragility, the diagnosis of hemolytic icterus is definite. The association of the latter with calculous cholecystitis is well known. If this is the case transfusions followed by splenectomy is the cure. The gallbladder disease can be considered later. It is further interesting to consider the possibility of hemolytic icterus in the child as the condition is frequently familial.

FRACTURE OF CERVICAL VERTEBRA

To the Editor—1 A boy, aged 16 with a fracture of the fifth cervical vertebra has slight anterior displacement of the fracture portion. The vertebrae are in good alignment. There was no evidence of nerve injury. He is in a helmet type plaster cast. How long should this cast be left on? What is the after-care when the cast is removed? Should he be permitted to play basketball or other games later? If so how soon? 2 A man aged 78 had a fracture of the bodies of the third fourth and fifth cervical vertebrae. The spines of the third and fourth are displaced markedly posteriorly. He has no displacement of the vertebra however. He had some involvement of the nerves in his arms which has since cleared up. How long should be the period of immobilization? He has the same type of a cast on and is up and about. Please omit name.

M D Wisconsin

ANSWER—1 In cases of fracture of the bodies of the cervical vertebrae, if the alignment is good and there is no evidence of nerve injury, conservative treatment includes complete immobilization, preferably in bed, for from four to six weeks. Immobilization with a plaster cast of the type described is then recommended for a period of at least six more weeks. If the helmet type of plaster cast is worn during this period of six weeks, it is advisable to graduate the patient from this to a collar made of plaster or reinforced cardboard, which can be worn for the final three weeks. Exercises that might include sudden or violent movements of the head are contraindicated for at least six months.

Physical therapy, consisting of heat and massage and carefully supervised exercises, may be recommended and aids in the recovery of strength in the muscles of the neck. Participation in competitive sports of any kind for a period of one year following the injury is unwise. If at the end of that time a roentgenogram shows a satisfactory appearance of the spine at the site of the fracture, if the patient has no disability or discomfort and if the range of motion is normal, restrictions with regard to activity may be withdrawn.

2 Fractures of the cervical spine in elderly persons, even without involvement of the spinal cord or nerve roots may be expected to result in some permanent disability. This may consist of stiffness and pain in the neck and not infrequently, pain along the course of the nerves the roots of which emerge at the site of the fracture. When there are three fractured vertebrae and the patient is 78 years of age immobilization should be continued for a total period of three months.

Some delay in the healing of the fracture in elderly persons can be expected. The end results in fractures of the cervical spine without spinal cord injuries or involvement of the nerve roots, and without dislocation, should be satisfactory. Not infrequently the fractured vertebral bodies fuse together producing slight but painless limitation of motion.

EPINEPHRINE OUTPUT AFTER INSULIN

To the Editor—In an editorial comment in THE JOURNAL June 23 page 2108 there appeared the statement. It was shown that an increase in the output of epinephrine occurred after the administration of insulin. Will you kindly cite the references on which this observation is based as well as any evidence to the contrary? What means were used to demonstrate such an increase? Are there any clinical manifestations following the injection of insulin that may be attributed to this increased secretion of epinephrine? Relevant references concerning clinical or experimental data would be appreciated. Kindly omit name.

M D Philadelphia

ANSWER—That insulin hypoglycemia brings about an increase in the secretion of epinephrine was shown experimentally by Cannon, McIver and Bliss (*Am J Physiol* 69 46 [June] 1924). As the sugar concentration falls after insulin injection a critical point is reached (between 70 and 80 mg per hundred cubic centimeters of sugar in normal cats) at which the discharge of epinephrine is at a maximum. Removal of both suprarenals or removal of one and denervation of the other before giving the insulin results in a progressive drop in blood sugar without augmentation of the epinephrine in the blood. That suprarenal-ectomized animals are very sensitive to insulin has been shown

(*Lewis Compt rend Soc de Biol* 80 1118, 1923. Hallion and Gray *ibid* 92 945 [April 3] 1925. Barnes and others *Proc M I* 31 524 1934). On the other hand, C F and Gerty T Cori (*J Biol Chem* 74 473 [Sept] 1927) concluded from experiments with suprarenal-ectomized mice that the epinephrine is not responsible for mobilization of carbohydrate from the liver during insulin hypoglycemia.

The indicator of suprarenal activity in this study was the denervated heart both stellate ganglions are removed and both vagi sectioned. Under fasting conditions an increase in epinephrine concentration in the blood results in an acceleration of the rate of the denervated heart. The denervated iris has also been used as an indicator of changes in epinephrine concentration (Abe *Arch f exper Path u Pharmacol* 103 73, 1924).

The rapid pulse pallor, sweating and dilatation of the pupils observed in insulin hypoglycemia are indications of sympathetic autonomic activity just as is suprarenal secretory activity. It is difficult to say to what extent the symptoms of insulin hypoglycemia are due to increased secretion of epinephrine or are influenced by it.

REINFECTION WITH TUBERCULOSIS

To the Editor—A number of the staff members of the institution with which I am connected have been interested in a question of some importance in a sanatorium for tuberculosis. Consultation of the literature has given contradictory results. What is the latest authoritative opinion as to the danger of one patient with pulmonary tuberculosis being further infected as the result of prolonged intimate contact (in the same room) with another patient with positive sputum who is careless about covering his mouth when coughing and is not careful in disposing of his sputum? Is there much danger of increased tuberculous infection or secondary infection being carried from one tuberculous patient to another? Please omit name.

M D Colorado

ANSWER—Experimentally, it is possible to contaminate an animal with tubercle bacilli for the first time and obtain a reaction that is not specific. On subsequent reinfection inoculations, a specific reaction does occur. There is almost as much difference between the foci of disease which result from the two inoculations as though one were dealing with two different disease entities.

In the human body the same difference in reactions to first infection and reinfection with tubercle bacilli may be observed through x-ray films, laboratory and clinical examinations, and at the postmortem table. The first infection nearly always results in a very benign lesion. The reinfection type of lesion is benign in some cases but causes nearly all of the illness and death from tuberculosis in the human family. Whether this reinfection is due to exogenous or to endogenous sources of tubercle bacilli is a subject that has been discussed at great length. Most students of this subject are of the opinion that it may be produced by either. The destructiveness of the reinfection with tubercle bacilli is dependent on the presence of allergy. Whether the tubercle bacilli escape from a previously existing focus or whether they are taken into the body through the common portals of entry makes little difference, since both are capable of producing tuberculo-protein, which in the presence of allergy is a deadly poison.

The high percentage of persons living in homes where an open case of tuberculosis exists, who later develop clinical tuberculosis is apparently good evidence that exogenous reinfections are of considerable significance. The more intimate the contact, the more frequent the clinical cases. Barclay (*Am Rev Tuberc* 26 192 [Aug] 1932), for example showed that approximately 27 per cent of the persons who sleep in the same beds as tuberculous patients later develop clinical tuberculosis. Recent studies on conjugal tuberculosis are also convincing. When sufficiently large numbers of consorts of tuberculous patients have been carefully examined with modern diagnostic aids and have been observed over sufficiently long periods, clinical disease develops in an alarmingly high percentage statements to the contrary notwithstanding. Recent reports have shown that approximately from 10 to 50 per cent of such consorts develop demonstrable lesions.

For years patients who had clinical pulmonary tuberculosis have asked the question whether they might develop more tuberculosis through close association with fellow tuberculous patients in sanatoriums. The answer of the medical directors of these institutions was almost invariably to the effect that the person who has tuberculosis cannot get more through exposure. On what evidence such an answer was based is now hard to determine.

Today it is known that over a period of years the multiple reinfection type of tuberculous lesions appears in the same body. In fact, it is a common experience to see the patient with tuberculosis in only one lung at some subsequent time have a lesion appear in the opposite lung. Whether this lesion is from

exogenous or endogenous sources cannot possibly be determined by present methods. Therefore, whatever is said about them in this respect must be largely a matter of opinion.

From the reports of Shaw (*Quart. J. Med.* 2:179 [April] 1933) and others on patients treated by sanatorium routine alone and traced approximately ten years later, one is led to wonder what effect reinfections from fellow patients had on the appearance of new lesions and the ultimate death of such a high percentage. When one realizes that, when artificial pneumothorax is instituted on the side of the only demonstrable lesion, a frequent complication is appearance of the disease in the opposite lung, again one wonders what part reinfections from fellow patients played.

Such students as Ronzoni, Brown, Opie, Harbitz, Webb, Rist (*Bulletin of the International Union Against Tuberculosis* 4:97 [April] 1927) and many others admit that exogenous reinfection occurs. Some are of the opinion that it occurs rarely, others believe that approximately 50 per cent of the cases of clinical tuberculosis are due to bacilli from exogenous sources. Therefore the exposure of one tuberculous patient to another in the same room or ward certainly is not entirely without danger.

BURNING OF HANDS AND FEET

To the Editor—A woman aged 80, unmarried has complained of intense burning of her feet and hands for nearly a year, the condition being exaggerated in warmer weather and after taking warm baths. The area complained of extends upward about 3 inches on the arms and legs, on the two sides alike. Examination reveals a diminution of the sense for sharp and dull over the whole body. Hot and cold are perceived normally. The dorsalis pedis arteries of both feet are normal. The superficial veins of the feet and hands are noticeable but not large. No varicosities of the leg veins have been observed. The color of the skin is normal, and the temperature of the extremities seems to be the same as that of the body even when the paroxysms of burning are present. The general health is good; there are no headaches, dizziness or general aches and pains. The blood pressure is 120 systolic and 60 diastolic, the pulse regular and the temperature normal. The blood count is within normal limits. The urine is normal. The Wassermann reaction was not taken. The weight is 90 pounds (41 kg.) the patient states that this weight has obtained for several years without much fluctuation. The reflexes are normal. Appetite and elimination are good. At times the patient cannot tolerate any hose on the feet, and frequently she goes barefooted. Even at night the weight of a thin sheet causes discomfort. Treatment for the past two months has consisted of warm and cold contrast baths to the extremities, massage with alcohol and fluidextract of ergot 10 drops three times a day. Some relief was noted at first but was only temporary. During the hot weather, benefit was obtained by using cool water to which she added a small quantity of vinegar. Kindly advise as to the possible diagnosis and further treatment in this case. Please omit name.

M D Indiana

ANSWER—The observations in this case would apparently rule out thrombo-angitis obliterans, Raynaud's disease and erythromelalgia. The age is above that at which so-called acroparesthesia usually begins, but this disorder is obscure and may well be the best diagnosis. A gradual occlusion of the finer vessels is probably the basis of the sensory disturbance. In this case it would be well to try vasodilators such as frequent doses of glyceryl trinitrate or rather large doses of theobromine sodiumsalicylate. Frequent examinations of the blood and reflexes should be made to rule out a beginning pernicious anemia in which cord changes are developing. A gastric analysis for free hydrochloric acid would be of interest.

SKIN GRAFTING

To the Editor—I have a patient whose thumb was cut off across the proximal phalanx with a rope. I do not wish to sacrifice the length of his thumb to get skin to cover the end so I think I will need to skin graft it. What type of skin grafting would you suggest to leave the least painful scar? Please do not publish my name. M D Texas

ANSWER—Ordinarily with a clean wound immediate grafting of full thickness skin is indicated and usually successful.

In this instance, in which some time has elapsed and granulation tissue has formed, the edges of the skin should be freshened and the granulation tissue pared down to a fibrous healthy bed. A full thickness skin graft may be cut from the inner side of the thigh or from the abdomen, all of the fat being carefully removed and only the skin being left. This graft should be fitted carefully to the defect in the end of the finger and the edges sutured with fine silk to the skin, with no extra skin and no tension. The graft should be covered with fluffed gauze or a sterile rubber sponge to maintain slight pressure over it. The dressings should not be changed for a week ordinarily and then the stitches removed and redressed until thoroughly healed.

In case of failure due to infection or a poor bed of tissue a split skin or Thiersch graft will more easily grow, although it is not so satisfactory.

SPOROTRICHOSIS IN DOGS

To the Editor—A wire haired fox terrier was presented for treatment of an abrasion of the left shoulder which the animal had been scratching almost constantly. During examination a pea sized flattened swelling was noted adjacent to the abrasion but was not regarded as being important. The abrasion healed in a week and the animal had ceased to scratch, but a new crop of small swellings appeared. They were sharply circumscribed deep hard lumps showing no tendency to break down or disappear until about fifteen days old when a few did open discharging a thick dark fluid. The rest gradually receded. During this time, however subsequent series of swellings appeared radiating from the first one following irregular lines along the abdomen, back and especially on the limbs hitherto unaffected, until one hind leg was swollen to twice its normal size. The swellings were cold and painless deeply situated, and each series seemed to be more severe than its preceding series. Local antiseptics and surgical treatment did not seem to help in any way. No organisms could be found in smears and there were no skin parasites present in or around the lesions. Two 10 cc. doses of metaphen were given four days apart by the intravenous route. Each dose was followed by rapid improvement of two days duration after which the swellings again appeared. As I had observed the effect of metaphen on molds during research work, a fungous infection was suspected and daily doses of potassium iodide 25 grains (1.6 Gm.) were administered. The swellings subsided entirely after the fifth day and no more appeared. The administration of potassium iodide was continued for two weeks, after which the animal was to be discharged. The duration of the disease prior to iodide treatment was ten weeks. The owner of the animal insisting on a diagnosis was told that the disease resembled sporotrichosis in man on which he became alarmed about the possibility of his family contracting the disease. Is this likely to occur? Can the animal be discharged as cured with assurance that the disease will not recur? To my knowledge this disease has not been reported in canine pathology but has been reported in horses. I will greatly appreciate any information you can offer.

ALFRED KISSILEFF, VMD Florntowo, Pa

ANSWER—Sporotrichosis of dogs has been reported in France by Cougerot and Caraven but so far has not been recognized in this country. The fox terrier's ailment as described seems to resemble closely sporotrichosis as seen in man, but, while affected dogs may present skin lesions similar to those observed in man, the canine disease according to Hutya and Marek is usually associated with inflammation of the bones and joints, leading to deformity. Nodules may form internally, causing symptoms of peritonitis. Since sporotrichosis can be transferred from animal to animal or to man by contact with infectious material, it is unfortunate that cultural methods were not employed in an effort to determine definitely whether or not the dog in question had sporotrichosis.

If the disease is sporotrichosis, it is possible that persons in contact with the affected dog may contract the disease. However, infection of human beings by dogs suffering from parasitic skin diseases is a rarity, though ringworm of cats can be transmitted. As for the probability of recurrence, even without reexposure to the original source, one cannot hazard an opinion.

EPIDERMOLYSIS BULLOSA

To the Editor—A girl aged 7 years has had since infancy large slightly raised red indurated, ulcerous, pustular lesions, which tend to heal very slowly and are at times covered by a thin crust. The ulcers are shallow. The lesions are located on the trunk and extremities, particularly on the legs. Usually three or four months is required for their healing. Several lesions were present for two years. Most of the lesions are about the size of a quarter (24 mm.) An injury anywhere to the skin is likely to result in a slowly healing indolent lesion such as described. Ten per cent ammoniated mercury ointment seems to be of some benefit. Lesions did not develop at the sites where a Pirquet test was made or at sites where blood for a Wassermann test and for a white cell count was drawn. The patient at one time lost all her finger nails. The child is mentally alert bright in school and plays actively like other children. The white blood cell count was 15,400. Urinalysis showed nothing abnormal other than a grade 1 albumin. The Pirquet and Wassermann tests were negative. General physical examination reveals nothing other than is already recited. The patient has red hair. What is the diagnosis of this case the prognosis the etiology of the disease and the treatment? Would autogenous vaccine be of any help here or would the intravenous administration of a substance such as dilute hydrochloric acid to raise the opsonin index, be of value? Would solution of potassium arsenite be of benefit? The lesions are tender to palpation. I will be grateful for any help or suggestions received. If published in THE JOURNAL kindly omit name. M D Illinois

ANSWER—This case is most probably one of epidermolysis bullosa. The lesions usually follow injury, and the changes described most probably resulted from secondary infection of the injured sites. The disease rarely disappears, although in a few instances the activity of the process has diminished at puberty, and the skin becomes more resistant to injury. The condition is usually congenital and hereditary, and its occurrence in different members of a family over several generations has been noted. Congenital absence of elastic tissue, a persistent thymus as a result of a congenital polyglandular syndrome, and a low grade inflammatory state associated with an angioneurosis have been suggested as etiologic factors. No

treatment thus far has had any specific effect on the process. Local protection to prevent injury to the vulnerable sites, with treatment as indicated to the injured areas, and the prevention of subsequent infection are used. Arsenic, calcium and viosterol have been used with indifferent results. It is not likely that autogenous vaccine or intravenous hydrochloric acid will have any special beneficial effect. Solution of potassium arsenite may be cautiously used.

CYSTS OF THE BREAST

To the Editor—A married woman aged 33, mother of two children, consulted me for a growth in the left breast. On examination I found it to be about the size and shape of a hen's egg. Its surface was smooth and of an unusual hardness. It was movable and not attached to the skin. I advised removal of the growth. The patient objected to any operation. The mother of the patient had a growth in her breast at the age of 45 and a radical removal of the breast was performed ten years later. A well advanced carcinoma was present at the time of operation. Being a very poor surgical risk, she died a few hours after the operation. The patient consulted me again in three weeks. The growth had enlarged to the size of an orange. I decided that it was a cyst and asked permission to drain it since she would not consent to its removal. Consent was given and 8 ounces (236 cc.) of a rusty (not amber) colored fluid was aspirated. Of course the cyst soon filled again. With her permission it was opened and packed with sterile gauze. After ten days the gauze was removed but the cyst continued to discharge. In the meantime another cyst developed. I insisted on its removal while it was still small. Consent was not given. The patient consulted a surgeon at Indianapolis who advised her not to have the cysts removed but only drained. He assured her that by this treatment the cysts in time would disappear. I told the patient that the surgeon might be right but that the process was too slow and the results uncertain. The case is now in the hands of another local doctor. What I want to know is whether I was wrong in advising removal of the cysts with a family history of carcinoma in the background. What is the consensus regarding the treatment of such cases? I can quote several living authorities to back my stand.

C. R. ELLERS, M.D., Sheridan, Ind.

ANSWER—Incision and drainage of cysts for cystic disease of the breast is generally not an accepted procedure. The method was used many years ago but has been largely discarded. From the description it is evident that the patient is suffering from cystic disease of the breast. The danger of cystic disease of the breast is that it is frequently complicated by an epithelial neoplasia, the extent of which cannot be determined clinically. It may be that the patient is suffering from purely cystic disease, but it is impossible from clinical examination alone to rule out the presence of Schimmelbusch's disease or even of microscopic cancer. There are numerous examples in which breasts presenting this clinical setting are removed and prove to harbor beginning cancer microscopically. The fact that there has been cancer in another member of the family renders this possibility even more likely. There can be little difference of opinion on the importance of surgical removal, the extent of the operation to depend on the extent of the disease.

SKIN LESIONS IN WORKERS HANDLING ZINC CHLORIDE

To the Editor—Small indolent boils without much inflammation or tenderness form about the hands and wrists of workers handling 65 per cent (?) zinc chloride in an industrial plant. When handling the solid zinc chloride the workers wear heavy rubber gloves. The drops and fumes of the zinc chloride come in contact with the bare skin while some heat or welding process is being used. Apparently no harm is done except when the zinc chloride comes in contact with minute or small scratches or abrasions. Following such accidents the hands are immediately washed and any such areas covered with campho-phenique or some petrolatum ointment. The sores and skin abscesses are very resistant to healing. I should like a fairly simple routine of prevention and one of treatment suggested. The workers apparently cannot prevent the minor scratches and abrasions in their other work and cannot wear protective gloves during the process mentioned. Immediate mercurochrome and flexible collodion to the latter minute injuries has been suggested for prevention besides their present treatment.

J. L. AIRD, M.D., Manhattan Beach, Calif.

ANSWER—Zinc chloride is a powerful caustic and usually produces multiple lesions on the fingers, hands and forearms of workers who come in contact with it. An eschar is produced at the sites of contact. The surrounding skin looks macerated, rubs off easily, and leaves an underlying white and bloodless surface. There is little sign of local inflammation, and the lesions may or may not be painful. The wearing of gloves is the best method of prevention. The use of some one of the protective creams applied to the hands may give partial protection. Treatment of the active lesions consist in removing the slough or eschar and filling the wound with sodium bicarbonate. A warm solution of sodium bicarbonate may also be used for a compress and then the lesion dressed with boric petrolatum, painted with mercurochrome or covered with metaphen in collodion.

IDIOPATHIC PRURITUS

To the Editor—A white man aged 66, complains of crawling, itching sensations between the shoulder blades on the scrotum in the axillae and occasionally on the skin of the head. These began two years ago while he was working at carpentry and living in a railroad boarding house. The skin over the areas is of fine texture with no redness or visible marks of irritation and parasites or eggs were not found. Daily baths and change of underclothes gives relief for a time. He feels all right if he goes to work after the bath but if he relaxes in a chair at this time the itching sensations return in about an hour. He is not sensitive to wood or to pollens. In the winter the skin seems dry and the sensations increase if he goes without bathing for a few days. He uses a strong soap which does not make the trouble any worse. If he works all day he feels all right and will sleep well. However, if he is idle the crawling sensation will become evident and he will become restless and weary. He has had no previous skin diseases or serious illnesses. There is no history of syphilitic infection. He has used a variety of treatments most of which were given for a parasitic infestation. I have been unable to find any evidence of parasites. Please omit name.

M.D. Iowa

ANSWER—No urine report is given, so examination should be made for sugar and the blood sugar level should be determined. In case of abnormal observations in either, the condition should be improved by regulation of the diet. The basal metabolic rate should be found and thyroid administered if needed. Some cases for which no explanation can be found are helped by the external use of some vegetable oil, such as olive oil.

TREATMENT OF SYPHILIS

To the Editor—I would appreciate some information as to how to handle this particular case. A white man, aged 49, contracted syphilis at the age of 22 while with the marines. He was given at that time three courses of mercury rubs during a period of six weeks. He never had a skin eruption or any other symptoms of the disease. He was married at the age of 34 and has six children living and well. The wife also is living and well and neither she nor any of the children has a positive Wassermann reaction. In 1931 he hurt one of the testicles which later gradually became rather large and during the following two years ulcerated three times. When he was seeking medical attention for this the blood Wassermann reaction was 4 plus. Since January of this year he has received two courses of bismuth preparations and two courses of neoarsphenamine. The testicle is practically down to normal size. The problem confronting me is that the Wassermann reaction is still 4 plus on the blood, but since he feels physically and mentally well and his family are all Wassermann negative he does not favor taking any further treatments. What are his chances of later syphilitic manifestations physically or mentally? What type of treatment do you advise? Please omit name.

M.D., Minnesota

ANSWER—This question is answered in detail in *Queries and Minor Notes* in *THE JOURNAL*, Nov. 4, 1933, page 1500.

More specifically, and with reference to this particular case, the inquirer should be certain that, in addition to the gumma of the testis, the patient may not also have cardiovascular or neurosyphilis. The spinal fluid should be tested immediately. If it is positive, treatment must be continued and modified with the idea of attacking the central nervous system involvement. If it is negative and if there are no clinical evidences of cardiovascular syphilis or neurosyphilis, the patient should be treated continuously for a total period of two years with courses of an arsphenamine alternating with courses of a bismuth compound, with approximately six courses of each drug being given. In the absence of involvement of the cardiovascular apparatus or central system, and with this arbitrary amount of treatment, the persistently positive blood Wassermann reaction may be disregarded.

SYPHILITIC AORTITIS

To the Editor—Please outline further types of antisyphilitic remedies to be used for a woman aged 42, with syphilitic aortitis and compensated aortic insufficiency. There are no other evident lesions. She has had full courses of arsphenamine, potassium iodide and sodium bismuth thioglycollate. The blood Wassermann reaction is still negative with alcoholic antigen 4 plus with cholesterol. The Kahn reaction is 4 plus. Please omit name.

M.D.

ANSWER—As a rule it is unwise to start treatment of an aortitis with one of the arsenicals. The healing effect is so rapid that there is actually local profound change in the walls of the aorta, which, in healing, may result in so much contraction that an actual insufficiency will be caused, a condition spoken of as a therapeutic paradox. In other words, the aortitis responds to the arsenical therapy, but in doing so an even more serious condition is brought on by the rapid healing, an aortic insufficiency. Consequently it is preferable in a case of aortitis to begin with intramuscular injections of a bismuth compound, for example, bismuth salicylate or potassium bismuth tartrate suspensions in oil, 0.1 Gm. intramuscularly once a week for a course of eight or ten injections. Accompanying this one might give 0.5 Gm. of potassium iodide three times a day. If the

patient stands this therapy well it might be possible to start in cautiously with neoarsphenamine, not arsphenamine, at least in the beginning. One should begin with an injection of 0.1 Gm and gradually work up to a maximum of 0.45 Gm in the male and 0.3 Gm in the female, administered once a week. Otherwise there is danger of too rapid healing of the aortitis and the possibility of a paradox ensuing. Under such circumstances the response of an aortitis, if it has not gone too far, to therapy is excellent, and alternating courses of neoarsphenamine and a bismuth compound, each of ten injections, should be given in the form of continuous therapy, i. e., a course of neoarsphenamine followed directly by a course of the bismuth compound and then by another course of neoarsphenamine, and so on until a period of at least two years of treatment has been given. While it may be interesting to make a blood Wassermann test, too much stress should not be laid on that. The factor of giving the patient so much treatment in two years would have far more bearing. Another thing that should be looked into carefully with all cases of cardiovascular syphilis is the possibility of an involvement of the central nervous system. Several different studies that have been recently made on cardiovascular syphilis have stressed the frequency of coincidental involvement of the central nervous system in some form of syphilis.

EMETICS IN LOBAR PNEUMONIA

To the Editor—Some treatises recommend emetics especially powdered ipecac, in children's lobar and lobular pneumonia, on the basis of elimination of the swallowed sputum with consequent prevention of absorption of toxins and perhaps microbes. Please explain if there is scientific ground on this procedure and if so what are the indications, contra indications and by effects? Kindly omit name. M.D. Brazil

ANSWER—There is no scientific ground for this procedure in either lobar or lobular pneumonia. Consolidated lung can neither be coughed up nor vomited up, and swallowed sputum is safely taken care of by bowel action. It is only in spasmodic croup and possibly also in capillary bronchitis when a spasmodic element is present and coughing is ineffectual in dislodging accumulated mucus that emesis might be permissible to aid in the removal of obstructing material by means of the powerful chest compressions that accompany the vomiting, as well as to favor relaxation of the spasm of the air passages in the depression succeeding the emesis. Marked weakness of the circulation contraindicates the use of emetics for this purpose.

DIATHERMY IN FRACTURES

To the Editor—Will you kindly advise me the present-day opinion on the use of diathermy in the treatment of fractures particularly with regard to its effect on callus formation?

O. O. FEASTER, M.D. St. Petersburg, Fla.

ANSWER—There are competent physicians who feel that diathermy is of real benefit in the treatment of fractures. Investigation has not established that diathermy hastens union or earlier callus formation or increased callus formation. In cases of delayed union, diathermy has been used without appreciable benefit. The administration of heat by diathermy in certain cases of painful, badly swollen fractures has been found of benefit in relieving pain and probably in hastening the relief of the swelling. Owing to the impaired circulation, great caution is necessary to prevent burning. Diathermy seems to be of little value in fractures, except for the relief of the symptoms.

SCOPOLAMINE

To the Editor—I have a friend who was diagnosed as having encephalitis three years ago. At that time he was advised to take one one-hundredth grain (0.6 mg.) of scopolamine (hyoscine) hydrobromide three times a day. He has continued this ever since and increased it up to five doses a day. He says he gets very nervous and feels crazy when he fails to take a dose and that a feeling of well being occurs a few minutes after he takes the usual dose. He is anxious to stop this habit and consulted me. Please advise me as to the habit forming quality of this drug the dangers of continued use and suggestions as to a possible cure for the addiction. Please omit name.

M.D. Arkansas.

ANSWER—If scopolamine hydrobromide were habit forming in its qualities, doubtless this would have come to the attention of physicians, since it has been in therapeutic use for many years. Solimann states that scopolamine has advantages over morphine by quieting the reflexes and by avoiding habit formation.

No deleterious effects have been described from its continuous use over periods of years. If this patient has sequelae of encephalitis that are relieved by the administration of this drug, it would seem quite proper to let him continue with it.

Should there be no reason for its continued administration, the drug may be withdrawn in diminishing doses over a period of a week or ten days. Sedative action may be supplied by the use of barbitals and wet packs or warm baths. The nutritional state of the patient and his general physical condition should be brought to its best possible level before withdrawal is begun.

EDEMA AFTER CIRCUMCISION

To the Editor—A man, aged 28 had a circumcision done under local anesthesia. The procedure consisted of injecting about 8 cc. of 1 per cent procaine hydrochloride (epinephrine) solution about the root of the penis and the mucous membrane of the prepuce, followed by a dorsal slit and removal of redundant prepuce. The ventral portion about the incision started to swell up following operation forming a constriction ring proximal to the edematous portion. There has been slight reduction of the baggy edema with relief of the constriction but the edema itself has persisted for six weeks now, in spite of heat applications. There is no infection or ecchymosis. I would welcome suggestions for relief of the edema. Please omit name.

M.D., Mass.

ANSWER—Probably there has been some interference with the rather scanty blood supply to the skin and subcutaneous tissues in this region. It is probable that within a few weeks more this edematous condition will clear up with no treatment at all. Alternating applications of heat and cold may stimulate the circulation to absorb the edema. If the edema persists after a few more weeks, one might excise the larger part of the edematous area. If there is a redundancy of foreskin with a narrow base, one should endeavor to free any pressure on this constricted portion. It is advisable that one use only 0.5 per cent of procaine hydrochloride with not over 2 minims of epinephrine solution to the ounce for circumcisions.

VACCINATION IN WHOOPING COUGH

To the Editor—A boy aged 6 years had whooping cough in May 1934 and was given four injections of pertussis vaccine as furnished by the state health department. No reaction resulted other than local swelling or redness. August 22 he received the first dose of diphtheria toxoid (alum precipitated) and five days later was ill with an acute respiratory disorder accompanied by fever and a generalized urticarial rash. This cleared in three days. I had understood that the toxoid had little or no protein in it and did not produce the protein reactions common to toxin-antitoxin administration. What is the relationship between the allergic reaction and the previous pertussis inoculation? He has had no other vaccines or serums and gives no history of hypersensitiveness. He is scheduled to have a second toxoid inoculation in one month. Should the regular dose be administered and if so is it likely that he will develop serum sickness again? Please omit name.

M.D. New York.

ANSWER—It is quite likely that the pertussis vaccine was made from Bordet bacilli, grown on a culture medium made with blood other than human. As it is quite likely that the one injection of diphtheria toxoid (alum precipitated) will immunize the boy, it would be best not to give him any further injections of it. A potent pertussis vaccine made from Bordet bacilli grown on culture mediums made with fresh, defibrinated human blood is now on the market. Such vaccine does not sensitize.

VIRCHOW'S GLANDS

To the Editor—Where are Virchow's glands?

L. A. CROWELL, JR., M.D. Lincolnton, N. C.

ANSWER—Virchow's gland or glands is the lymph node or nodes behind the clavicular insertion of the left sternomastoid muscle near the termination of the thoracic duct at the junction of the left subclavian and internal jugular veins. Virchow called attention in 1849 (*Die medizinische Reform*, 1849, p. 248) and earlier to the fact that in carcinoma in the abdomen, secondary growth not infrequently develops in these lymph nodes and that in doubtful cases of abdominal tumors such secondary localization might be of great diagnostic help.

KEITH'S LOW IONIC DIET

To the Editor—A patient of mine has a marked retention of fluid. She is on Keith's low ionic diet. I should like to know whether there is a salt substitute that can be used without harm to this patient.

M.D.

ANSWER—In using Keith's low ionic diet, no salt or a salt substitute is used. The difficulty with vegetable salt for seasoning is the sodium ion present. In connection with this diet, potassium nitrate or potassium chloride may be given and used to season food. Potassium chloride is more palatable, but potassium nitrate is a better diuretic. It can be given in a dosage of from 5 to 10 Gm daily.

FRACTURE OF CLAVICLE IN NEW BORN

To the Editor—Will you kindly tell me the best method to treat a simple fracture of the clavicle in the new born, incident to birth trauma? How long is the usual time required for this type of fracture to heal? Kindly omit name

M D West Virginia

ANSWER—The best method of treating a simple fracture of the clavicle in the new born is to strap the shoulders back by means of figure-of-eight turns that include both shoulders after the axilla have been very carefully padded. The usual time required for healing is between ten and twenty-one days

RUBEFACIENT OINTMENT

To the Editor—Will you please send me a formula for the preparation of something approximating the composition of the commercial rubefacient ointments? It is necessary for me to have something that is cheap and still acts as a good mild counterirritant for colitis, bronchitis and similar disorders. Even camphorated oil is expensive here

GEORGE H RUE M D Seoul Chosen China

ANSWER—The following rubefacient ointment might meet the requirements

Mustard Ointment

Powdered mustard	16.0 Gm
Water	30.0 cc
Mix and add	
Rosin cerate	60.0 Gm
Oil of turpentine	15.0 cc

Rosin Cerate

Rosin	35.0 Gm
Yellow wax	15.0 Gm
Lard	50.0 Gm

SCLERODERMA OR RAYNAUDS DISEASE

To the Editor—In connection with the reply in the M D from Ohio published in THE JOURNAL November 17 page 1558 under the title of Scleroderma or Raynaud's Disease may I call your correspondent's attention to the recent report of Leriche and Jung. Le chlorure d'ammonium dans la thérapeutique de la sclérodémie. *Presse méd* 41:1041 (July 1) 1933 in which they report the successful treatment of two cases of extensive scleroderma following the use of daily administrations of 3 Gm of ammonium chloride in combination with an acid forming (ketogenic) diet

The theory underlying the treatment is to increase the elimination of calcium following the physiologic acidosis. This the authors were able to demonstrate by means of calcium determinations on the urine and blood. It was interesting to note that the discontinuance of ammonium chloride and the ketogenic diet and the substitution of parathyroid extract previously used unsuccessfully caused the recurrence of symptoms but a return to the acid diet and the administration of ammonium chloride caused the scleroderma to disappear again

It did seem that in a case in which the ultimate prognosis is so poor as in that described by the correspondent a trial of this method would be in order. However in addition to the operative measures mentioned in your reply I think the question of a parathyroidectomy should be considered

GEORGE V KULCHAR M D San Francisco

PARANAVEL COLIC

To the Editor—In THE JOURNAL November 17 page 1562 is a request concerning the nature of paranael colic so frequently encountered in children. In your discussion little mention is made of one of the most common etiologic factors of this type of pain, i.e. throat infection. Dr Joseph Brennemann of Chicago was one of the first clinicians in this country to call attention to the importance of the abdominal pain of throat infections in children. Following is a bibliography of Dr Brennemann's contributions to our knowledge of this most distressing symptom

- The Abdominal Pain of Throat Infections *Am J Dis Child* 22:493 (Nov) 1921
The Clinical Significance of Abdominal Pain in Children, *Surg Gynec & Obst* 34:344 (March) 1922

INCUBATION PERIOD OF RABIES

To the Editor—The question asked by M D South Carolina (THE JOURNAL December 1 p 1726) is one that arises so frequently that I am venturing a comment. You are correct in regard to the incubation period of rabies in dogs. Also the policy advocated by the state laboratory director of South Carolina as to the ten days observation of biting dogs is correct. The apparent inconsistency referred to by the inquirer is explained by the fact that the saliva of an animal in the incubation stage of rabies does not become infectious until from two to five days before active visible clinical symptoms set in. Therefore the bite (or scratch) of a dog in the incubation stage is noninfectious provided the animal remains free of symptoms for a period of ten days following the date of the bite. In such cases we have found seven days to be a sufficient period of observation of the biting animal

Brooke Bland MD Francis L. Lederer BS MD and A. Graeme Mitchell MD Volume XI RIC TEL Fabrikoid. Price \$120 per set of 12 volumes and Index. Pp 1111 with illustrations Philadelphia F. A. Davis Company 1934

Previous volumes in this series have been reviewed in THE JOURNAL from time to time. Volume ten is devoted largely to a discussion of pregnancy, parturition and the puerperium, to the prostate, to psychoanalysis and psychiatry, and to radiology concluding with an important discussion of diseases of the rectum. Between these major headings are sections, of course, devoted to other alphabetical subjects falling in these limitations. The contributors include among the obstetricians such names as those of Adair, Barnes, Bland, Cooke, Norris and Bethel Solomons, on the genito urinary side, Hugh Young, Hunt and Caulk, in psychiatry, Bond, White and Ebaugh in proctology, Bacon, Rosser, Friedenwald and Dudley Smith and in radiology, Pfahler and Kirklin. Such names as these attest the high character of this work.

The eleventh volume is of equal quality. The leading headings include rickets, scarlet fever, scurvy, diseases of the skin, of the spinal cord and of the spleen, and the stomach, then come the sympathetic nervous system and syphilis, with all the other alphabetical headings intervening. The volume is printed with a narrow column in large type but the illustrations are hardly so profuse as they might be in an encyclopedic work of this character. The usefulness of an extensive reference work of this character is, of course, well known.

Manipulative Treatment for the Medical Practitioner. By T. Martin MD M.B. Ch.B. Medical Officer in Charge of the Massage Electrotherapeutic and Light Departments University College Hospital London. Cloth Price \$3.75 Pp 133 with 86 illustrations. New York Longmans Green & Company London Edward Arnold & Company 1934

This is evidently the work of a physician who has tried to see the good in manipulative therapy. He tries to understand the underlying pathologic changes in the bone and joints and their contiguous structures. He has indicated some of the dangers that may befall the manipulative therapist. He has made what appears to be an honest effort to evaluate the benefit of this form of therapy. He calls attention to the fact that, unfortunately, bad results of the bone setters never gain so much prominence as the few occasional cures. People are willing to gamble with their health. They like to decry the orthodox doctor and credit the quack with some supernatural powers of healing. He speaks of the wealthy horse dealer who would not entrust one of his valuable horses to any but the best veterinarian but who would entrust the care of his beautiful daughter to a bone setter concerning whom he knew nothing. He considers treatment by manipulation under four headings: (1) reduction of dislocation, (2) forcible breaking of adhesions, (3) soft tissue manipulation and (4) manipulation of joints in which no actual dislocation has occurred but there is a slight defect the nature of which he is unable to describe, or understand. He emphasizes the point that joint manipulation should be undertaken only by specially skilled persons. The chief object of manipulation is to produce tissue relaxation. In the treatment of the soft tissues, one must recognize that two conditions exist: fibrositis and local spasm of muscle, and the success of the treatment can be objectively gaged only by the complete relaxation of the tissues. In the discussion of the choice of cases for manipulative treatment he presumes that all grave organic diseases have been ruled out. The cases in which this treatment is indicated are chiefly those presenting joint or soft tissue involvement, i.e., injuries that call for readjustment of bones or joints. Adhesions must be prevented or, if already present, should be broken down gradually or forcibly under anesthesia. He includes also cases of fibrositis and certain cases of rheumatic joints. Forcible manipulation should not be undertaken while a joint is acutely inflamed, nor is it easy to determine how soon after that the joint may be manipulated. He calls attention to the fact that in arthritis, although there are changes in the joint, the pain is chiefly in the tissues surrounding the joint. The author believes that manipulation should be regarded as a branch of physical medicine.

Jahresriete Innenansicht eines Menschenlebens. Von Alfred E. Hoche. Paper Price 4.50 marks. Pp 298 with 1 illustration. Munich J. F. Lehmanns Verlag 1934

This is the autobiography of a German professor of psychiatry who has seen much of normal and abnormal life in private practice and before the courts. He has accumulated a fund of experience with which he illustrates and illumines his narrative. As a life history it can be classed among the honest autobiographies, not too much space is given to personal matters and there are interwoven with observations on motives of conduct, a profound and frank discussion of the nature of personality, the life of the spirit, the relations of youth to age, the meaning of life, religion, the balance of happiness and the significance of death. To the oft repeated question 'Which is the most valuable, a biography or an autobiography?' this book adds its support to the claims of the latter. Such a study of the problems of life combined with, and growing out of, the portrayal of the life of an individual could hardly be given in an outside view of a human life. An honest self portrayal of an eventful life when made by a trained and skilful writer is a valuable contribution to literature.

Hygiene for Freshmen By Alfred Worcester A.M. M.D. Sc.D. Henry K. Oliver Professor of Hygiene Harvard University Cloth Price \$1.50 Pp 151 Springfield Ill & Baltimore Charles C. Thomas 1934

This book presents a series of twelve lectures given by the author as a brief required course in hygiene for Harvard freshmen. The purpose, as stated in the preface, is "to save the student from the possible distraction of note-taking." The subjects of individual lectures range from biology and embryology to glands, mental hygiene, reproduction and immunity. Clearly the author is attempting to provide his students with a background of embryology, anatomy, physiology and immunity. Although highly desirable, this is a more ambitious program than most teachers who are trying to interest college freshmen in the subject of health would wish to undertake in a series of twelve lectures. It is disappointing to find in a book such careless and inaccurate statements as

The comfort of normal salt solutions applied to fresh wounds or to the eyes

The white blood corpuscles have nuclei some of them several. They are formed in the lymphatic glands.

Normally within a few minutes after violent exercise both the heart in action and size returns to normal. [Gordon shows that the heart tends to be diminished in size immediately after strenuous exercise (*Am J Roentgenol* 14:424 [Nov.] 1925 abstr. *THE JOURNAL*, Jan. 23 1926, p. 304)]

It is a question whether they [vitamins] have yet been isolated and their exact composition revealed by the biochemist

The discovery of the insulin cure of diabetes

The pneumococcus is practically always to be found in the mouth

In the World War when vaccination [against typhoid] was compulsory there were very few cases and no deaths

In the chapters on mental hygiene and reproduction, the author gives adequate information for a book of this sort. In his emphasis on masturbation and homosexuality he is led into statements that would be difficult to verify and might be disturbing to the average undergraduate. In general, the lectures contain much interesting and authoritative material, but they go into unnecessary detail on some points, such as the anatomic description of the mammary and sweat glands and the definition of zygote, morula, gastrula, ectoderm, mesoderm and endoderm, while other subjects of more general interest are treated superficially or entirely neglected.

The Etiology and Treatment of Spasmodic Bronchial Asthma. By H. Gordon Oliver M.D. With a foreword by W. Langdon Brown M.D. F.R.C.P. Regius Professor of Physic Cambridge University Boards Price 3s. 6d. Pp 48 with 10 charts London H. K. Lewis & Company Ltd. 1934.

There is still too much speculation about the etiology of bronchial asthma. The treatment likewise is complicated and in many cases unsatisfactory. There can be no doubt that asthma is an allergic disease and that pollens and foods play a most important part. The author in a brief monograph reports fifty cases observed in ten years. In all of these the fungus *Monilia* was found in the sputum and the patients were all benefited by iodides and a vaccine. He courageously concludes that all cases of asthma are due to a mycotic infection of the *Monilia* organism. The number of cases, however, is too small and they are too localized to justify such definite conclusions.

Mortality Among Patients with Mental Disease. By Benjamin Malzberg Ph.D. New York State Department of Mental Hygiene Albany Cloth Price \$1.50 Pp 234 with illustrations Utica N. Y. State Hospitals Press 1934

It has long been known that death rates among patients with mental disease are greatly in excess of those of the entire population. Despite all that modern medicine can offer, the death rate of the insane remains relatively high, as evidenced from statistics concerning rates of mortality and causes of death among patients under treatment in the New York civil state hospitals during the three fiscal years July 1, 1928-June 30, 1931. Even when due allowance is made for age differences in the two populations, the death rate of the patients remains in excess in the ratio of almost 5 to 1. The death rates are highest in the organic psychoses and lowest in the functional group. There are marked differences in the relative distribution of the causes of death. In the general population of up-state New York the leading causes of death are, in order, diseases of the heart, cancer, nephritis, cerebral hemorrhage and pneumonia. Among the mental patients the causes of death in order

of frequency were diseases of the heart, pneumonia, dementia paralytica, tuberculosis, diseases of the arteries, nephritis, cerebral hemorrhage and cancer. These and other interesting data are thoroughly discussed in the comprehensive booklet. Attention is also called to various factors responsible not only for the real but also for a spurious excess of the mortality of patients with mental disease over the mortality of the general population. The book will be of great interest to those interested in vital statistics.

Industrial Maladies. By Sir Thomas Legge CBE M.D. DPH. Edited by S. A. Henry M.A. M.D. DPH. H.M. Medical Inspector of Factories Cloth Price \$4.25 Pp 234 with 13 illustrations New York & London Oxford University Press, 1934

This volume is in a way a memorial to its author, who died just before its publication. He was eminent as a British authority in the field of industrial disease control. In Great Britain he was recognized as among the leaders in research against industrial disease. He gave the Lowell lectures at Boston and the Cutter lecture in preventive medicine at Harvard in 1929. He lectured also on the history of medicine and on related subjects. The book deals more fully with those phases of industrial medicine which concern its author, although lead poisoning and health welfare conditions in factories receive a great deal of space. A bibliography of the writings of Dr. Legge shows a vast amount of work carried on in the years 1893 to 1932.

Benjamin Rush Physician and Citizen 1746-1813. By Nathan G. Goodman Cloth Price \$4 Pp 421 with 8 illustrations Philadelphia University of Pennsylvania Press 1934

The name of Benjamin Rush has been commemorated in the United States in many institutions and in many notable works, yet there has thus far been available no full biography and no worthwhile appreciation. Physicians realize that Rush contributed notably to the beginnings of American psychiatry, that he was active in the development of the College of Physicians, that he aided in the development of many movements for reform, and that he was active as a citizen and a political leader. Only recently his writings on focal infection have been reprinted in various places. In this conventional biography the author traces the career of Benjamin Rush chronologically from his early years and medical apprenticeship to studies at Edinburgh, the building of his practice and his growth as an educator and a man of affairs. The volume is made especially interesting by the quotation of personal correspondence and of journalistic and other writings of the times. There is, of course, a most extensive study of the relationship of Rush to the control of the great epidemic of yellow fever. The volume is a fine contribution to the list of notable American medical biographies.

Wege zur Verhütung der Entstehung und Ausbreitung der Krebskrankheit. Von Prof. Dr. Bernh. Fischer-Wasels, Direktor des Senckenbergischen Pathologischen Instituts der Universität Frankfurt a. M. Paper Price 2.70 marks Pp 75 Berlin Julius Springer 1934

The author prefaces his contribution with the statement that his views are theoretical and have not been demonstrated clinically so far as human cancer is concerned. The discussion begins with a good review of the causes of cancer, including general factors, constitutional predisposition and external irritants. The work of Reding and Slosse dealing with alkalosis in cancer is discussed. General intoxication of the organism resulting from tar and arsenic and indole is taken up in detail. In discussing metabolic changes associated with cancer, the author states that it is necessary to avoid fermentation and that one must on the one hand increase the respiration of the organism and on the other hand depress fermentation and production of lactic acid. By eliminating alkalosis he proposes to strengthen the resistance of the body against cancer. Since insulin generally depresses fermentation, the use of this agent is suggested with the belief that, by building glycogen from sugar, tumor growth will be depressed. Based on these theories, a detailed program of prophylaxis and treatment of cancer is suggested. He advises against marriage of individuals with a strong hereditary tendency to cancer. In order to diminish the alkalosis of the body he suggests the inhalation of 5 per cent carbon dioxide but admits that it has not been successful in the treatment of human cancer when a malignant tumor had already become established. On account of these discouraging

results he advises against it but suggests it as a prophylactic measure in individuals who have reached the cancer age. The administration of splenic extract is advised in order to stimulate the reticulo-endothelial system. A detailed dietary regimen is outlined, based on the conception of avoiding alkalosis. It is evident that the author has a genuine and serious interest in the cancer problem and is motivated by a keen desire to alleviate the suffering occasioned by this disease. In this commendable effort, however, he has based a highly impractical therapeutic formula on evidence much of which does not withstand critical analysis. As a review of the theories of causation, this publication has a distinct value, but as an aid in the practical treatment of the disease much time must elapse for laboratory study and clinical investigation to substantiate or refute the theories on which the conclusions are based.

Mothers' Guide When Sickness Comes. By Roger H. Dennett, B.S., M.D., D.Sc. and Edward T. Wilkes, B.S., M.D. Cloth. Price \$2.50. Pp. 400. Garden City, N.Y.: Doubleday, Doran & Company, Inc. 1934.

From time to time in recent years, books have been published that are intended to aid the mother in carrying out the doctor's orders and to help her in the recognition of sickness in the child, so that the services of a physician may be secured as soon as possible. These books are far different from the old-fashioned doctor's book, which encouraged self-treatment and produced much fear of disease. In this book there is an attempt to answer for the mother many questions concerning the child's diet, constipation and bad habits. It is simply written and well arranged. Such subjects as the sickroom, the function of the doctor, good and bad habits, birthmarks and teething are discussed. In addition, diseases and ailments—contagious and non-contagious—are described. The facts given are correct and are presented in a logical, common sense manner. It is to be hoped that the book will fulfill the purpose for which it is written and not contribute to the encouragement of self-medication.

Industrial Toxicology. By Alice Hamilton, M.D. Harpers Medical Monographs. Fairclough. Price \$3. Pp. 3+2. New York & London: Harper & Brothers, 1934.

This volume is one of a series of monographs. It concerns particularly those phases of industrial disease in which its author has been especially interested. However, for purposes of completeness there is also a general consideration of industrial poisoning, after which many common poisons are discussed under various headings and classifications. The book is well written and is supplemented by an adequate bibliography and an index. At this time when the diseases of industry are attracting so much attention, it will be found exceedingly useful by many physicians.

What About Alcohol? An Illustrated Outline of Scientific Facts About Alcohol and Alcohol Drinking. By Emil Bogen, M.D. and Lohmann, W.S. Hisey. Preface by Haven Emerson, M.D. Cloth. Price \$1.50. Pp. 112. With illustrations. Los Angeles: Angelus Press [for the Scientific Education Association], 1934.

This volume proposes to provide a simple understanding of the relationship of alcohol to human physiology and health. It is not a volume of propaganda, although the facts about alcohol are in themselves propaganda against its use in many instances. The book is simply illustrated with line drawings that are highly instructive. The book is supplemented with a bibliography and an adequate index.

Out of the Test Tube. By Harry N. Holmes, Ph.D. Cloth. Price \$3. Pp. 373. With 83 illustrations. New York: Ray Long & Richard R. Smith, 1934.

The advances of chemistry have made life much happier and interesting for all of us. The new book by Holmes may take its place beside the already known works of Slosson as a contribution to the popularization of chemical knowledge. The chapters are numerous and short but they cover a great range of topics in the chemical field. The titles of the separate chapters are such attractive statements as "The Importance of Nothing at All," "The Lightest Substance Known," "Brimstone or Cornerstone," "Sugar and Sweetness, and Fats to the Front." While it is not extensively illustrated, a number of line drawings add to the interest afforded by this most interesting book.

Medicolegal

Validity of Regulation Excluding Unvaccinated Children from School.—The board of education of the Fort Worth (Texas) Independent School District passed a regulation excluding unvaccinated children from school. The plaintiffs sought by injunction to compel the board to permit their children to attend school without being vaccinated. The trial court dismissed the action and the plaintiffs appealed to the court of civil appeals of Texas, Fort Worth.

The plaintiffs contended that since the Texas constitution requires the subject of a bill to be expressed in its title, the title of the act creating the Fort Worth Independent School District (Special Acts of 39th Legislature, c. 230) was not sufficiently indicative to permit the insertion in the body of the act of provisions purporting to permit the board to require the vaccination of pupils. The title of this act recites, among other things, that the act gives to the board power "to make rules and regulations for the government and conduct of said schools, and for the protection of those attending said schools." We think the title, said the court of civil appeals, is sufficient to advise the legislature as well as any other person reading it that the body of the act might authorize, as in fact section 36 does authorize, the board to "require the vaccination of pupils and teachers whenever it may become reasonably necessary or proper."

The plaintiff next contended that in Texas vaccination can be required by a board of education only when there is an emergency or threatened epidemic of smallpox and that there was no threatened epidemic at the time the regulation was passed. It is not a question of emergency, said the court, but of whether the action of the board was arbitrary and without facts on which minds could have decided rationally that such rules were reasonably necessary. The court takes judicial notice of the fact that vaccination against smallpox is an efficient and accepted act tending toward immunization. This and other similar discoveries of preventive medicine have inspired those who guard the public health to strive to keep the public from getting sick and the law must lend its hand and keep pace with scientific advance. Even though there was no immediate epidemic in the locality, the Supreme Court thought that the action of the board was not arbitrary and unreasonable, in view of the fact that smallpox may spread from distant points, and the further fact that the school district involved in this case had a large Negro and Mexican population, "which races are generally known to be more difficult to keep free of smallpox for various reasons."

The order of the trial court dismissing the bill was affirmed.—*Booth v. Board of Education of Fort Worth Independent School District (Texas)* 70 S. W. 2d 350.

Criminal Abortion. Civil Liability of Physician, After-Care Requirement Dependent on Contract.—Where a husband and wife consent to the performance of a criminal abortion on the wife, said the Supreme Court of Idaho, they cannot thereafter maintain a civil action against the operating physician to recover damages for injuries allegedly due to the physician's negligence. Consent to the illegal act constitutes a bar to the recovery of damages. If a physician who performs a criminal abortion contracts to render necessary after-care in his office only, failure on his part to attend the patient at her residence does not constitute negligence.—*Nash v. Meyer (Idaho)*, 31 P. 2d 273.

COMING MEETINGS

American Academy of Orthopedic Surgeons, New York, Jan. 14-16. Dr. Philip Lewin, 104 South Michigan Boulevard, Chicago, Secretary.
American Orthopsychiatric Association, New York, Feb. 21-23. Miss Mary A. Clarke, 50 West 50th Street, New York, Secretary.
Annual Congress on Medical Education and Licensure, Chicago, Feb. 18-19. Dr. William D. Cutter, 535 North Dearborn Street, Chicago, Secretary.
Pacific Coast Surgical Association, Santa Barbara, Calif., Feb. 21-23. Dr. Edgar L. Gilcreest, 384 Post Street, San Francisco, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to fellows of the Association and to individual subscribers so THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

18:949-1182 (Nov.) 1934

- Osteopetrosis (Marble Bones) in an Infant. Review of Literature and Report of Case. D. J. McCune and C. Bradley. New York—p. 949.
- Subacute Peritracheal Pneumonia. H. S. Reichle and A. R. Moritz. Cleveland—p. 1001.
- Carbohydrate Metabolism. II. Role of the Thyroid Gland. J. A. Johnston. Detroit—p. 1015.
- Body Build in Infants. IV. Influence of Retarded Growth. II. Bakwin Ruth Morris Bakwin and Lillian Milgram. New York—p. 1030.
- Basal Metabolism of American Born Chinese Girls and of American Girls of Same Age. C. C. Waag. Cincinnati—p. 1041.
- *Preliminary Report of the Fels Fund Study of Fetal Activity. L. W. Sontag and R. F. Wallace. Yellow Springs, Ohio—p. 1050.
- Factors Influencing Utilization of Calcium and Phosphorus of Cow's Milk. J. H. Hess, H. G. Poncher and Helen Woodward. Chicago—p. 1058.

Osteopetrosis in an Infant—McCune and Bradley review the literature of osteopetrosis. The cases that have been diagnosed and reported up to 1933 are tabulated. They present a case report with metabolic and hematologic data. There is no evidence at present to suggest that osteopetrosis is due to endocrine disturbance, environmental factors, dietary deficiency or chemical poisoning. Although it is possible that there are inconstant associated changes in the calcium and phosphorus metabolism, these alterations, if present, are probably secondary manifestations of a primary disturbance in the formation of bone. The Albers-Schonberg syndrome is a true developmental disease that consists in faulty differentiation of the primitive common forerunner of osteogenic and hematogenic tissue. The ultimate cause of the abnormality is unknown, but it seems to be a property of the parental germ plasma.

Study of Fetal Activity—Sontag and Wallace call attention to the desirability of a more extensive interest in the behavior of the human fetus. A description of the work of the Fels Fund on fetal activity is presented and the following points are emphasized: (1) the relationship of fetal activity to such factors as variations in maternal emotion, maternal ingestion of food, maternal and fetal position and maternal fatigue, (2) the response of the fetus or lack of response to certain stimuli and the ensuing refractory period, (3) the possibility of conditioning the human fetus and (4) the relationship of fetal cardiac rate and prenatal respiratory movements to certain physical and emotional factors in the mother.

- Influence of Dietary Deficiency on Transmissibility of Trachoma to Monkeys. R. A. Hettler and W. M. James. St. Louis—p. 1048.
- Nonpigmented Nevus of Lacrimal Caruncle. E. A. Shumway. Philadelphia—p. 1055.

Allergy Theory of Sympathetic Ophthalmia—Friedenwald investigated whether the histologic observations in sympathetic ophthalmia were compatible with the theory of allergy. The relation of melanin granules to the specific histologic

features of the inflammation in the uveal tracts, retina and skin revealed that allergy to uveal pigment is an adequate explanation of these characteristics. However, allergy to uveal pigment may be present without sympathetic ophthalmia. If the theory of allergy is correct, some additional factor other than allergy is therefore necessary to initiate the disease. A study of the Dilen nodules sometimes found in sympathetic ophthalmia suggests that the additional factor may be a proliferation of the melanophores. The results of some preliminary experiments based on this hypothesis suggest that the additional factor required for the initiation of the inflammatory reaction is a proliferation of the intraocular melanophores. Based on this hypothesis the author has treated three patients having sympathetic ophthalmia with ultraviolet radiation, exposing their bodies to an erythema dose of the radiation three times a week with careful protection of their eyes and faces. The indicated local treatments and salicylates were, of course, given at the same time. Of the three patients, two were children. Both made complete recoveries. The third patient was an old man with bilateral cataracts and senile dementia, who developed a typical bilateral uveitis following cataract extraction on one eye. He was given the foregoing treatment, the inflammatory reaction became quiet, but both pupils were bound down by dense adhesions, so that his vision was reduced to light projection. Further operations could not be performed because of his mental condition.

Calcium Stream and Healing of Fractures—The observations of Moore and de Lorimier emphasize several aspects as to the assimilation and utilization of the osseous inorganic elements. When the diet and additional administrations were such as to allow an acid medium in the intestine (by lactose fermentation) and an alkaline tissue balance there resulted an increase in the urinary excretion of calcium and inorganic phosphorus, and since there was no evidence of osseous depletion (instead a furthering of ossification of callus) there was evidently an increased assimilation of these elements through the intestinal wall. Though the excretions were greater when ammonium chloride was administered, it was found that the blood values for the calcium and inorganic phosphorus were decreased, moreover the ossification of callus was delayed and there was a generalized deossification of the skeleton. The assimilated calcium, in this second situation, then was not utilized—the calcium stream was directed away from the skeleton. The fact that some ossification did occur is not inconsistent with this general idea. It is reasonable to believe that this is due to a relative alkaline balance in the callus or to the added stimuli resulting from reaction to the injury. When sodium bicarbonate was added to the diet, there is evidence that assimilation was hampered, and though the blood calcium was decreased there appeared at least favorable utilization of the osseous elements in the skeleton—that is, in this third situation the "calcium stream," though relatively reduced was directed toward bone. This emphasizes

the fact that for assimilation of calcium and phosphorus the chyme in the small intestine should be acid, but for the utilization of these elements the tissue balance should be alkaline.

Röntgen Therapy of Epitheliomas of Pharynx and Larynx—During 1931 and 1932, Lenz and his associates treated thirty-one verified epitheliomas of the pharynx and larynx by a modification of the Coutard method of röntgen therapy. Fourteen patients have remained clinically well from nine to twenty-four months following cessation of the treatment, in seventeen cases the disease was not arrested. Twenty-four of these cases were considered proper for evaluation of the method of treatment and of the criteria used for prognosticating its success or failure. Of twelve cases classified by microscopic criteria as radiosensitive, nine were arrested by treatment, while none of the ten cases classed as radioresistant were arrested. Two cases in which the criteria were conflicting have been arrested by treatment. The authors believe that their study confirms the experience of others that among the factors militating against successful treatment are (1) extensive infiltrative growth, especially if it is associated with deep infection, and (2) tumor invasion or local nutritional changes of the laryngeal cartilages, because such processes reduce the radioresistance of cartilage and favor chondronecrosis. Tracheotomy did not interfere with the treatment in their cases, whether done before or after the course of röntgen therapy. The results reported are early and may change with time. However, the authors believe that they are sufficiently encouraging to warrant continuation of this method of röntgen irradiation in the treatment of epitheliomas of the pharynx and larynx.

Operation of Thick-Walled X-Ray Tubes on Rectified Potentials—Taylor and Stoneburner find that thick-walled glass, high voltage therapy x-ray tubes do not reach a steady state within the first few minutes of operation on some types of generator. All thin-walled tubes tried thus far quickly reach a steady operation state. Depending on the mode of control of the generator, the röntgen emission of a thick tube may increase or decrease by from 10 to 20 per cent on mechanical or valve tube rectifiers and not reach a steady state until some ten minutes after starting. The change in röntgen emission between the second and tenth minute of operation appears to depend on the electrical regulation of the transformer. Partial cooling of the walls of the tube with strong air blasts delays the attainment of the steady state but does not affect the magnitude of the net change in emission. For some generators the output remains steady if the effective tube current and voltage are maintained constant. A qualitative explanation of the effect is based on the blocking action of the high negative charge on the glass walls when the tube is cold. As the tube warms up this charge is dissipated through the increased electrical conductivity of the glass. The influence of the effect on dosage measurements is discussed. The effect is absent when the tube is operated on nearly constant potential.

Treatment of Coma—Bauer recommends the intramuscular injection of liver extract in coma following hyperemesis eclampsia, operative procedures, extensive burns, myocarditis

and persistent vomiting, that is, coma due to edema of the liver caused apparently by a breakdown of protein. During the process of increased breakdown of proteins, the liver is unable to get rid of the numerous products of the broken down proteins. Whenever the pyrimidin nucleus cannot be broken down any further, "autonarcosis" of the organism is likely to occur. The sudden dramatic improvement due to injection of liver extract, as seen by Hammerschlag and the author, may well be explained by the assumption that the organism apparently is liberated from the broken down protein products, which have a narcotizing effect, as the result of the increased fermentative liver action. The rapid beneficial effect of injection of liver extract in nonnephritic uremia makes a fermentative, hormone action all the more likely, as most of the patients are not anemic. It may be considered possible that the substances in liver extract which counteract the tendency to coma are not formed in the liver but only stored in it, like the "antipernicious" principle which is formed in the stomach but found in the tissue of the liver.

Metabolic Stimulants and Sodium Dinitrophenol—Bortz states that sodium dinitrophenol 2-4 is capable of causing a notable reduction in weight. If used without regard to a planned diet, that is, a reduction diet of from 700 to 1,000 calories, loss of weight will not be striking, although it will still take place. Used with caution, the drug should prove to be a valuable adjunct in the treatment of persons who find it difficult or impossible to lose weight by the usual established method. Dinitrophenol acts most satisfactorily in patients with the exogenous type of obesity. Those having pituitary or gonadal glandular deficiency often tolerate the drug badly or not at all. In two patients having mild myxedema, a heightening of thyroid activity approaching the thyrotoxic state was observed after three weeks of treatment, in this event, immediate cessation of dinitrophenol therapy is imperative. The drug is not a substitute for thyroid extract. It is exceedingly unfortunate for the public that no law now exists to prevent the indiscriminate dispensing of powerful drugs such as the dinitro compounds. The therapeutic dose of 300 mg. daily administered in three doses of 100 mg. each is but one tenth to one third of that dispensed freely over drug counters today. The author has knowledge of persons who have taken from fifteen to thirty times this quantity and were not under the care of a physician. He urges that sodium dinitrophenol and allied chemical compounds be included in the list of dangerous drugs, the control of the use of which should be governed by the federal Food and Drugs Act. That sodium dinitrophenol, dinitrocresol and other metabolic accelerants are of real value for the reduction of body weight in certain selected patients who find it impossible to reduce by limitation of diet is no doubt true. The author, however, does not unreservedly recommend their use and desires to stress that, when the medical profession arouses itself to its obligation of service to persons requiring or wanting to reduce their body weight and outlines a sensible regimen to this end, the diet sanatoriums and quacks and charlatans will have a diminishing financial return and the general health of the community will be benefited greatly.

Blood Cholesterol and Creatine Excretion in Urine—Hess discusses the value of estimating the blood cholesterol and excretion of creatine in the diagnosis and treatment of thyroid deficient children. The blood cholesterol is high in children with untreated hypothyroidism and is reduced by thyroid medication. The level of blood cholesterol may be used as a guide to the efficacy of thyroid therapy. The metabolism of creatine appears to be influenced definitely by thyroid activity during childhood. During the period from infancy until about puberty, creatinuria is physiologic. Hypofunction of the thyroid causes a decrease or complete cessation of creatine excretion which can be restored to normal values after the administration of thyroid extract. This is accompanied by a corresponding change in the clinical condition of the patient. The creatinuria is a delicate index of the effect of ingested thyroid since it occurs before any definite change is noted in the basal metabolism and blood cholesterol. From a comparison with other diagnostic criteria of hypothyroidism in children, the change in creatine metabolism appears to be an important observation that may be useful in diagnosis and in the control of therapy.

Epidemic Arthritic Erythema—Place and Sutton give a complete report of the epidemic (named epidemic arthritic erythema) that occurred in January 1926 in a confined area of Haverhill, Mass. The only previous epidemic of a disease similar to this of which they have found a record occurred in May and June 1925, at Chester, Pa. Although the nature of the epidemic was not determined there was a striking similarity of onset, symptoms and course and epidemiologic relation to the milk supply of the two outbreaks. The disease is characterized by an abrupt onset, often with a chill, a rubellaform to morbilliform eruption, often scanty, chiefly on the extremities, with a tendency toward hemorrhage into the lesions and an inflammation of the joints with marked pain and tenderness not infrequently of prolonged duration. The disease occurred as a markedly localized epidemic and was undoubtedly spread through the raw milk supply. The organism Haverhillia multiformis, described only once before at Chester as belonging to the Mycobacteriaceae in the order of Actinomycetales, is believed to be the cause, having been found in the blood stream in eleven of the seventeen cases in which cultures of the blood were taken and in the fluid of the joint in the two cases in which cultures of the fluid were taken. Agglutinins were present in the blood of the infected persons but absent in the controls. Cutaneous reactions to killed suspensions were present in 83 per cent of the patients tested late in convalescence although absent in the controls. Although crippling may be marked for a time, recovery tends to occur in from one to two months, with a small number of patients having persistent joint symptoms. No fatalities occurred.

Effect of Theobromine on Peripheral Vascular Disease—Scupham found that theobromine and its salts, particularly theobromine sodium acetate, act as peripheral vasodilators. They are useful in the treatment of peripheral arteriosclerosis and early cases of thrombo angitis obliterans in which there is a large element of angiospasm. Their use results in subjective improvement in intermittent claudication, and repair of the loss of the integrity of the tissue has been noted. They are not effective in all cases, but the results obtained with them are sufficiently good to make them a valuable adjunct in the treatment of peripheral vascular diseases. Many patients in whom a good response was expected failed to improve. This has been particularly true in cases of diabetic arteriosclerosis and gangrene. In none of these cases has it been evident that theobromine was responsible for improvement that could not be accounted for by proper control of the diabetes and the complicating infection. The mode and location of the action of these drugs can only be surmised. The fact that they are

without effect in purely functional disorders, as in Raynaud's disease, and are most active in disease of the medium sized and smaller arteries, in which an element of angiospasm may exist, suggests that the effect may be a local one, possibly that of reducing the increased irritability of the musculature of the diseased wall of the vessel. This interpretation is in agreement with the views of Solimann and Pilcher, who stated that caffeine is a vasodilator acting by peripheral inhibition of vasoconstriction. Coronary arteries are of the same class of vessels.

Convulsions Due to Hyperinsulinism and Cerebral Lesions—Grayzel investigated whether or not repeated convulsions for varying periods of time induced artificially in rabbits by the production of hyperinsulinism, would lead to organic lesions in the brain. Animals that have not had convulsions, or only slight ones on a few occasions, show either minimal or no cerebral changes, regardless of the number of injections of insulin they have received. However, even one convulsion, if prolonged and severe enough, may produce definite lesions in the central nervous system. The more prolonged or the more severe the convulsions, the more extensive are the lesions found, provided the animals are permitted to live long enough for the changes to develop. What the exact mechanism is that produces the cerebral lesions in the rabbits cannot be stated definitely, but it seems to the author that during the convulsions some circulatory disturbance takes place with consequent anoxemia of the brain. During the more severe convulsions, these periods of anoxemia are sufficiently prolonged to cause the cerebral changes.

Autodesensitization of Allergic Conditions—Johnston found that whole blood, withdrawn from the cubital vein and injected at once deeply into the gluteal muscle promptly relieved several patients suffering from eczema especially the moist variety. One severe case of psoriasis of long standing was cleared up in three months. The patients' complaints of pain and soreness following the deep injections of blood and the occasional difficulty in locating the vein led the author gradually into the use of urine. The urine was rendered sterile, or as sterile as possible, before it was used hypodermically or intramuscularly. It was thought to be necessary that, in order to be of value in desensitization, the allergens must not be destroyed or changed, which would probably be the case if heated. Different antiseptics were added to the urine, in turn. The urine, after thorough filtration, was allowed to stand for forty-eight hours after the antiseptic was added, then cultures were made, and only sterile solutions were used. Graduated doses were given every three or four days, and not more than 9 cc. was injected at any one time. Each solution was kept under refrigeration. 50 cc. was prepared at a time and used continuously until finished, when a fresh specimen was procured and 50 cc. again prepared. All injections were administered under strict aseptic routine. The cases treated included arthritis, myalgia, neuritis, colitis, asthma, hay fever, urticaria, eczema, rhus poisoning, migraine, rhinitis, psoriasis and pruritus. The best results were obtained in the eczemas. Several cases of myalgia were relieved entirely. No patient with neuritis admitted being helped. One arthritic patient was relieved of a painful colitis while being treated unsuccessfully for arthritis.

Another arthritic patient received no benefit, but a migraine of a duration of years disappeared during the course of treatment. Asthma in children seemed to respond better than that found in adults. Hay fever, urticaria and migraine responded to this treatment in several instances.

Nonspecific Antigenic Factor in Mammalian Serums—Simon found a patient having vasomotor rhinitis highly sensitive to horse serum and equally sensitive to the serums of a variety of different mammals. Local passive transfer of hypersensitivity to these serums was successful. Skin tests to the raw muscle extract of chicken mackerel and codfish and to the serum of the frog and of men who belonged to different blood groups were negative. The identity of the antigenic principle present in the various mammalian serums that gave positive skin tests was apparently demonstrated by desensitization of passively sensitized skin sites. The antigen is not soluble in strong alcohol, it is precipitated by complete saturation with ammonium sulphate but not by one-half saturation. Boiling destroys it to a great extent but not completely. It is not affected by heating to 56 C for one hour. The presence of a species nonspecific antigenic factor in mammalian serums is not

incompatible with the existence of other factors that are species specific. The patient, as a boy, had had some contact with horses, but he stated that he had never had an injection of horse serum, even a dose of the diphtheria toxin antitoxin mixture. He did not remember ever seeing a guinea-pig. The possibility of a common, heterophile antigen was considered. Intradermal tests with serum in concentration greater than 1:1000 may be dangerous. The intradermal test in this case was about 1,000 times more sensitive than the scratch test. The conjunctival test was somewhat less sensitive than the scratch test. A purified horse serum globulin solution contained the antigen but in much lower concentration than normal horse serum. Antiserums made from mammals other than the horse will not necessarily eliminate serum accidents.

Granulocytopenia Due to Hypersensitivity to Amidopyrine—Drugs of the type represented by amidopyrine are recognized as frequently responsible for various manifestations of drug hypersensitivity, and Squier and Madison feel that the granulocytopenia observed after amidopyrine is the result of such a reaction. In support of this hypothesis they have produced granulocytopenia at will on readministration of amidopyrine to persons who have had the acute disease following the use of the drug. Furthermore, in two patients they have obtained positive skin reactions to patch tests with amidopyrine, with depression of the granulocyte count and clinical symptoms identical to those observed on administration of the drug by mouth. They report these two cases in detail.

Disseminated Lupus Erythematosus—In forty seven cases of disseminated lupus erythematosus, O'Leary found twenty-six showing clinical evidence of tuberculosis in one form or another. Tuberculosis was demonstrated in five of the ten cases that came to necropsy. The principal changes in the necropsy material were tuberculosis, endocarditis, infarcts in the spleen, diffuse nephritis and terminal bronchopneumonia. Pleural effusion and ascites from passive congestion were noted quite often. Anemia and leukopenia were present in half the cases. Cultures of the blood were positive in four attempts of twenty four made in fourteen cases. Of the four positive cultures, two were obtained from patients with endocarditis, the third was obtained while the patient was dying. Focal infection was noted in forty cases. The twenty patients having the acute type died, on the average, nine months following the dissemination of the disease whereas eight of the twenty-seven patients with the subacute type died, on an average, four and a half years following dissemination. Seven patients with the subacute type are cured apparently. Treatment of the subacute type consisted of rest in bed, transfusions of small amounts of blood, administration of quinine, plasmochin, small doses of gold sodium thiosulphate and roentgen irradiation of the glandular regions of the body. The evidence suggests that disseminated lupus erythematosus is a toxemia in which tuberculosis plays an insignificant part and that evidence of a specific infectious agent although suggestive, is still lacking.

*Early Recognition of Peripheral Venous Thrombosis M A Rabinowitz and I N Holtzman, Brooklyn—p 973

Peripheral Venous Thrombosis—Rabinowitz and Holtzman believe that fatal pulmonary embolism is most frequently caused by peripheral venous thrombosis of the lower extremities. A certain type of person is apparently constitutionally predisposed to this complication. Allergic factors, as yet insufficiently understood, may play a part in the production of venous thrombosis. Persons confined to bed for any reason whatever should be questioned daily for pain and tested daily for tenderness of veins of the lower extremities, especially during the second week of their stay in bed. Early diagnosis of venous thrombosis of the lower extremities should be followed by prompt and complete immobilization to prevent fatal embolization. The presence of sudden chest symptoms or signs occurring in the predisposed person should lead to immediate investigation for evidences of peripheral thrombosis, and proper precautions should be taken.

Transmission of Influenza by Filtrable Virus—Francis states that, in the course of the experimental work of inoculating intranasally into ferrets material from three specimens of sputum obtained from the recent epidemic of influenza of Puerto Rico, one of the laboratory workers developed symptoms typical of influenza. Nasal and pharyngeal washings inoculated intranasally induced the disease in a ferret without producing pulmonary consolidation. This strain was also transmissible from animal to animal with bacteria-free material. The results confirm the observations of Smith, Andrewes and Laidlaw on the transfer of a filtrable, transmissible agent from human cases of epidemic influenza to ferrets. The character of the disease in the ferret differs from that described by these authors in that it is more severe and is accompanied by pulmonary consolidation. In these respects the disease in the author's animals appears to resemble more closely the disease produced in ferrets by Shope with swine influenza virus. There has been evidence to suggest the adaptation of the virus to the ferret, for with one Puerto Rican strain distinct pulmonary lesions were first noted in the sixth passage animal. The results of the experi-

ments, both in ferrets and in mice indicate that the agent producing the disease is a filtrable virus. It has been possible to produce the infection with filtrates that are bacteriologically sterile in aerobic and anaerobic cultures. The pulmonary lesions are bacteria free. The microscopic changes of the involved lung resemble those of pulmonary lesions produced by other virus infections, rather than those of bacterial infections. The results are apparently in complete agreement with those obtained by Andrewes, Laidlaw and Smith.

Mechanics of Absorption in Intestinal Obstruction—Donaldson and Stout believe that there has been too much disproportion of detail regarding the treatment of intestinal obstruction, with insufficient attention and coordination of fundamentals of toxin production and absorption. They agree with the theory that the usual lethal toxin concerned is produced by intestinal tissue which is suffering from impoverishment of blood supply. Their experimental work indicates that the lymphatic canals of the mesentery are an important potential route for toxin absorption and that the lymphatic canals of the nonstrangulated mesentery are persistent in their patency—remaining patent for days after venous thrombosis and much edema have supervened. Exteriorization of the gangrenous intestine with temporization for a better clinical condition is as a rule poor surgery, because mesenteric lymphatic absorption of toxin continues. Immediate resection should be done. Anastomosis may be postponed until a later date. Peritoneal absorption of toxin occurs in proportion to the toxicity and permeability of intestine in the cavity. Clinical differentiation should be made between arterial and venous mesenteric thrombosis. Venous mesenteric thrombosis is a relatively benign condition as compared to arterial thrombosis, and recovery in man without surgical intervention may occur occasionally after venous thrombosis. The ability of intra-intestinal gas pressure to produce impoverishment of the blood supply of the intestinal wall should never be forgotten. This distention may produce all degrees of toxicity and even death. The laws of toxin production and absorption in complete intestinal obstruction necessitate in most cases the earliest possible relief of the organism from toxin dosage, and all temporization procedures, if used, should be handled with the greatest care.

Obstetric Methods—Theobald states that a binder during labor is strongly contraindicated. Instead, the woman should sit up or adopt any convenient attitude that allows the fundus to fall forward. In this type of case the head tends to remain well above the pelvic inlet until the cervix is at least half dilated and until after the rupture of the membranes. The width of the pubic bone gives some help in estimating the difficulty of any given labor. In 846 confinements, cesarean section or induction of labor was not resorted to in the treatment of contracted pelvis or of the toxemias of pregnancy. Twelve of thirteen infants were born spontaneously with the occiput in the posterior position. The forceps rate was less than 35 per cent. The morbidity rate (fifteen cases) was, it is believed, the lowest recorded by any hospital in England. Rendering the urine alkaline during the puerperium by administering potassium citrate is of importance in preventing morbidity. A technic for preventing mastitis and breast abscess is given. The value of the prophylactic use of antistreptococcus serum is stressed. The maternal mortality would be lessened if midwives were not allowed to make vaginal examinations. The increasing maternal mortality rate must be attributed to increased operative intervention. If the present policies are continued, a still further increase may be anticipated during this decade. There were sixty-eight stillbirths and neonatal deaths, twenty-six occurred in pregnancies of thirty weeks or less, fourteen infants were dead on admission, one was hydrocephalic and another microcephalic, and six were markedly premature (three being twins). Of the remaining thirteen cases the death of the fetus was due to lack of operative intervention.

 *Some Unusual Forms of Plague. A. W. Williams—p. 229
 Ointment for Use in Treatment of Ulcers C. H. Brennan—p. 233

Unusual Forms of Plague—Williams reports five cases of plague of unusual clinical type. In each case a disease of quite different prognostic and clinical features was simulated, and none could be diagnosed as either bubonic or pneumonic plague. All were seen as inpatients in an area in which bubonic plague is endemic and local outbreaks of pneumonic plague occur from time to time. Buboes were absent in the cases and pulmonary lesions, when present, were not those of pneumonic plague. Three of the five patients were ill for eight days or more and one actually recovered. The assumption is that these

cases were examples of a septicemia of less virulence than is usual in infections with *Pasteurella pestis*. The author believes that cases of this type are more likely to find their way into the hospital than cases of bubonic or pneumonic plague and are likely to be diagnosed wrongly and, if undiagnosed, to be a source of danger to the nursing attendants when the plague bacilli are present in the sputum. The only logical practice seems to be, during an outbreak of plague or in an endemic area, to examine sputum smears for *Pasteurella pestis* not only in cases clinically resembling pneumonic plague but in every case of pneumonia admitted to the hospital. The cases were divided into (1) septicemic plague resembling toxic jaundice of yellow fever type, (2) septicemic plague resembling primary meningitis, (3) plague resembling pneumonia with delayed resolution and recovery, (4) plague resembling lobar pneumonia and (5) a history of fever of a duration of four days, cough with purulent sputum and diarrhea. *Pasteurella pestis* was found in the smears and cultures of all the cases.

Treatment of Celiac Disease—Pritchard is of the opinion that celiac disease is due mainly to improper diet and especially to an insufficient supply of the essential vitamins during early childhood, particularly vitamin B. The line of treatment that he presents is based on the assumption that the primary cause of the disease is an actual defect in the functions of absorption, which may or may not be associated with a general atrophic thinning out of the mucous membrane of the intestine, and also with considerable dilatation of both the large and the small intestine. Fats should not be restricted, for they constitute under normal conditions one of the most favorable sources of roughage and ensure a solid consistency of the stools. If fats are eliminated from the celiac patient's diet, soaps cannot be formed in the intestine and there can be no good basis for a solid stool. The stools should be examined chemically and the presence of any considerable quantity of neutral fat, that is to say, unsplit fat, is a definite indication for the oral administration of some pancreatic preparation. If celiac patients are fed exclusively on a sugar diet for a short time, as is necessitated by the carrying out of the author's system of treatment, frothiness of the stools will disappear entirely. Fruits and vegetables are included, in that these, apart from milk, must serve as the almost exclusive sources of both vitamin and mineral elements. Protein foods are restricted, owing to their liability to undergo decomposition changes in the intestine and thereby increase the offensiveness of the stools and the dangers of intestinal intoxication, which is the chief cause of the serious troubles of celiac disease—the wasting, the nervous symptoms and the relapses. The treatment of celiac disease, if it is to be rational and successful, must take into account the atrophic and atonic condition of the whole of the alimentary tract. Since owing to these disabilities comparatively little food can be absorbed, it is necessary to conserve the limited amount of nutritive material that is capable of reaching the blood stream. For this reason, all unnecessary loss of heat should be avoided by keeping the child warm and well clothed. All wasteful output of energy should be obviated. The amount and type of food employed in the author's method are given.

*Role of Spleen in Water Metabolism Test of Splenic Retraction After
Salyrgan J. Fliederman — p. 601

The Spleen in Water Metabolism—Fliederman observed twenty patients with enlarged spleens but without hydrops, edema or enlarged livers. They were given 2 cc of salyrgan intravenously in the morning at rest. They were weighed before the injection and four and twenty-four hours afterward. The quantity of water in the blood was determined by the Bang method before and 10, 20, 30, 60, 120 and 240 minutes after the injection. The twenty-four hour secretion of urine was noted for three days preceding the experiment and each day of the experiment. During two hours before and four hours after the injection the hourly volume was determined. The volume of the spleen was determined before and every fifteen minutes during the first hour after the injection of salyrgan. It was then determined every hour for the first three hours and finally twenty-four hours after the injection. The dimensions are indicated in centimeters: (1) the distance between the superior pole found by percussion and the farthest advanced lower point found by palpation, and (2) the distance between the most distant external border and that nearest to the linea alba. As a result of these observations he concludes that usually following injection of salyrgan there is an energetic contraction of the spleen in one or both diameters. At the same time considerable hydration of the blood is produced, increased diuresis results, and there is a considerable loss of weight. These changes authorize the conclusions that (1) the contraction of the spleen after the injection of salyrgan is caused by the expulsion of residual water of the spleen into the general circulation and from there in the urine and extra-renal elimination, (2) the spleen functions as a water reservoir which empties itself after salyrgan injection, and (3) there often exists an increase in the water reserve in the diffuse splenomegalies. There is practical importance to the post-salyrgan splenic retraction. It is useful in the differential diagnosis of splenomegalies of different causes and in the study of different functional systems of the spleen. The absence of such contraction seems to have a certain prognostic importance in that it has been observed in all the cases in which roentgen therapy has been ineffective. Finally, the production of splenic retraction may relieve patients having a large painful spleen.

Journal d'Urologie Méd et Chirurgicale, Paris

38: 193-288 (Sept.) 1934

*Radical Curetting of Posterior Urethra E. Franceschi — p. 193
Traumatic Lesions of Kidney and Their Treatment. R. Redi — p. 231
*Treatment of Varicocele by New Surgical Method Z. do Amaral —
p. 249

Curetting of Posterior Urethra—Franceschi has been impressed by the cystoscopic appearance of the urethral crista in cases of posterior urethritis. In some cases it is possible to see inflamed and visible orifices that are catheterizable, and in others it was impossible to see any orifice. In many such cases he has practiced electrical curetting with superficial patting of the crista. Finally it was decided to attempt systematic destruction of the crista in the more serious cases. His purpose is to make certain that the products of massage of the vesicles and prostate are not obstructed at their orifices at the crista. Radical curetting of the posterior urethra consists in destruction by coagulation (1) of all diseased parts cystoscopically visible between the membranous sphincter and the bladder neck, and (2) of the diseased crista. In order to control the good results it is necessary to observe the disappearance of all changes previously noted with restoration of the urethral mucosa to normal, and the disappearance of the swelling of the crista and its replacement on the smooth urethral surface by one or more openings of the canals normally existing at this level and which have been amputated. The treatment outlined is easily given to ambulatory patients.

Treatment of Varicocele—Do Amaral describes an operative treatment for varicocele, which he considers an improvement over earlier methods. It consists in an incision similar to that for inguinal hernia. The aponeurosis is separated as far as the inguinal ring and the cord exposed up to the testicle. The testicle is exteriorized by gentle traction on the cord or by compression of the testicle from below. The varicose veins are found and isolated, care being used to avoid rupture of the anastomoses. The sheath is inverted and fastened in place by two or three catgut sutures. The afferent canal and arteries and the accessory veins are separated from the dilated veins and placed under the oblique and transverse muscles, which are in their turn sutured to the crural ligament with catgut as in inguinal herniotomy. The testicle is replaced with avoidance of a position close to the pubis and without torsion of the cord. The varicose veins may then be removed in the classic manner. The aponeurosis of the oblique is sutured and the skin closed. The author usually uses local anesthesia and occasionally spinal or general anesthesia.

Extra-Uterine Pregnancy in Presence of Intra-Uterine Pessary—Meyer-Wildisen reports the history of a woman aged 32, the mother of several children who in order to prevent further pregnancies used an intra-uterine pessary. Six months later she had uterine hemorrhages. Because an injury of the uterus or an extra-uterine pregnancy was considered probable, she consented to an operation, at which the uterus was found intact, but the right uterine tube was found to be greatly enlarged and to contain placenta-like tissues. The tube was resected and recovery was uneventful. The author cites other reports from the literature and stresses that intra-uterine pessaries do not always prevent pregnancy. The use of a pessary involves dangers to the woman employing it, and the author thinks that physicians should reject this method.

Chloroprivic Azotemia—Bunewitsch calls attention to the fact that in recent times increasing numbers of cases of chloroprivic azotemia have been reported. As a result of the loss of chlorides by diarrhea, vomiting, withdrawal of ascitic fluid or similar conditions, uremic symptoms develop and the examination of the blood discloses a high rest nitrogen content. Opinions on the relationship between this azotemia and hypochloremia are still divided. According to his theory, water and sodium chloride are secreted in the tubules, and urea, uric acid and so on in the glomeruli. A molecular exchange takes place in the glomeruli, an equivalent amount of sodium chloride is reabsorbed again by the glomeruli and water is likewise taken up again, effecting a concentration of the urine in the glomeruli. Thus if the nitrogen excretion is conditioned by the molecular exchange, the quantity of nitrogen in the urine will decrease proportionately to the amount of sodium chloride present in the kidney for this exchange. If the organism loses considerable amounts of sodium chloride the kidney loses corresponding amounts, and consequently the nitrogen elimination is curtailed and azotemia develops.

High Frequency Currents and Blood Pressure—Von Fischer says that the influence of high frequency currents is considered by some as merely suggestive, while others consider them highly efficacious. When they were introduced by d'Arsonval (1897) it was pointed out that they influenced the vasomotor system and reduced the blood pressure. The author studied the influence of high tension high frequency currents on the blood pressure of thirty-three persons by means of an apparatus with a tension of 220,000 volts and a frequency of from 800,000 to 1,000,000. In summarizing, he states that a single irradiation generally reduced the maximal pressure and had only a slight effect on the minimal pressure. The reduction of the maximal pressure was absolutely and relatively higher the higher the initial pressure had been. In case of

repeated applications, the results were similar to those of the first one. Regular repetitions of the treatment produced a lasting effect, which as a rule became manifest in a stabilization of the maximal pressure at a lower level. In case of abnormally low initial pressure, an increase may be effected in the maximal pressure.

 Nitrophenine (Alpha Dinitrophenol [1:2:4]) in Obesity Dupuy —p 744

Cholesterol, Ergosterol and Vascular Sclerosis—Gordonoff says that through the administration of cholesterol to rabbits, along with their feedings, an experimental arteriosclerosis is produced with lesions that are anatomically and functionally the same as those observed in human arteriosclerosis. If, instead of cholesterol, ergosterol is given to the rabbits, arteriosclerosis also develops as long as the animals are exposed to direct sunshine for a sufficient length of time. The skin of man is a depot of ergosterol, which becomes activated by the influence of ultraviolet radiation. Ergosterol, as soon as it is activated by the ultraviolet radiation, enters the circulation and, under certain conditions especially related to the reaction of the blood pressure with hyperpressure may be assimilated by the vascular system to produce arteriosclerosis. The author believes that there is a causal relation between the metabolism of the sterols and the development of human vascular sclerosis. He calls attention to the fact that male and female sex hormones are sterols, that there is a close relation ship between the female hormones, the corpus luteum and cholesterol, and that senile sclerosis is in physiologic antagonism to the sex hormones in youth. He believes that the mentioned facts seem to indicate the possibility of treating sclerosis by means of sex hormones in the near future.

Alterations of Leukocytes by Tuberculin Test—Navarro Marco and Luis Cíezar made determinations of the leukocytic formula immediately after the injection of Koch old tuberculin and half an hour after the injection in a group of tuberculous and nontuberculous persons. The authors conclude that the intradermal tuberculin test is followed by changes of the blood formula in half of the number of cases of the whole group. The most marked variations consist in a diminution of the lymphocytes or an increase of the eosinophils. Both variations are more frequent in tuberculous than in nontuberculous persons. The diminution of the lymphocytes is most marked between the ages of 18 and 26. The increase of eosinophils is most marked between the ages of 12 and 18. In both cases, sex has no influence on the variation.

Roentgen Characteristics of Hypertrophy of Thymus—Acuña and Vallino report two cases of hypertrophy of the thymus in nurslings. They say that in order to give a correct interpretation to mediastinal roentgen shadows it is advisable to make (1) the roentgenograms in the frontal view with the infant upright and during inspiration (2) the profile roent-

genograms with the infant in the lateral view, so as to obtain the shadows of both the anterior and the posterior aspects of the mediastinum, and (3) a roentgenoscopy with the infant in different positions. By using this technic it is possible to avoid diagnostic errors due to insufficient or defective technics. The roentgen aspects of the mediastinal shadows, however, are multiple, because of the individual variations of the gland. The most certain criterion for the diagnosis is the response of the condition to roentgen therapy, since the application of roentgen irradiation rapidly exerts a beneficial action on the enlarged thymus, as proved by the clinical improvement and by the regression of the thymus, visible in the roentgenograms. The results of the therapeutic test by themselves, however, cannot be considered of an absolute diagnostic value, but only when they confirm those of the clinical and roentgenologic examinations. The authors conclude by saying that one should be cautious in making a diagnosis of hypertrophy of the thymus in nurslings and that the diagnosis should be based on the results of the clinical and roentgenologic examinations confirmed by those of the therapeutic test.

 Diagnostic Cancer Tests M Bing and G Marangos —p 417

Stone-Free Stasis Gallbladder—The concept of stasis gallbladder implies, according to Schrader, an increased inflow of bile and retardation of the outflow. This study has for its aim the determination of the clinical significance of the stasis gallbladder and its ability to produce symptoms. In 140 cholecystectomies performed at the Göttingen clinic, 115 gallbladders contained stones while twenty-five were stone free. Before removal of the gallbladder, it was aspirated and the bile was submitted to the culture method of study, as well as to sedimentation and microscopic examination. The author describes three types of sediments: (1) granular crystalline bilirubin mucus, (2) drop-like brown-green partly stratified sediment and (3) a calcium microlith made up of calcium and protein resulting from damage to the liver. None of these could be said to be specific for a stone free stasis gallbladder. The histologic method of study consisted of removing a longitudinal strip of the wall of the gallbladder from the fundus down to the cystic duct. Acute cholecystitis was not found in a single instance. A frequent alteration consisted of accumulations of lymphocytes and of plasma cells in the mucosa, and of extravasated eosinophil leukocytes and edema together with young connective tissue in the submucosa. These alterations extended into the muscular and the fibrous layers. The lymphocytes always predominated. Suppurative processes, abscesses of the wall characteristic of acute cholecystitis, were never observed. A striking alteration was observed in the lymph vessels of the serosa and subserosa—an ascending lymphangitis. According to the author, this lymphangitis was not the result of a subsiding acute cholecystitis, since the bile in every instance was found to be sterile and free from leukocytes. These gallbladders were thin walled and did not exhibit any evidence of healed suppurative processes such as scars. The clinical picture corresponded to the histologic picture. There was no fever or icterus. A slight tenderness in the area of the gallbladder and a sense of pressure in the epigastrium were usually present. Because of the constant alterations found in twenty out of the twenty-five gallbladders examined, such as scars, inflammation and edema, it is not necessary to invoke stasis as the cause of colic. In this material there were no instances of a functionally dyskinetic stasis gallbladder as described by Westphal. Of the five cases that presented no pathologic alterations, colic persisted in two after removal of the gallbladder. Adhesions about a normal gallbladder or a narrow cystic duct do not constitute an indication for its removal. Evidence of ascending lymphangitis, adhesions about the neck, or enlarged lymph nodes in the area of the cystic duct make removal of the gallbladder advisable.

- *How Does Mucin Act on the Stomach? Mahlo and Mulli —p 1632
- *Early Diagnosis of Syphilis H T Schreus —p 1633

Action of Mucin in Stomach—Mahlo and Mulli maintain that, in addition to the protective action against thermic and mechanical influences, the gastric mucus also has certain colloid chemical functions. The most important of these the capacity to absorb acid and to release it again by diffusion, is still in dispute. In order to gain a better insight into the acid-combining capacity of the mucus the authors purified mucus by electroanalysis, that is, they removed all carbonates, phosphates and organic compounds of low molecular nature. The mucin obtained in this manner has not lost its binding capacity for hydrochloric acid. The authors state that the adsorptive action is also chemical, for the ionization of the mucin increases together with the hydrogen ion concentration. This was demonstrated in conduction measurements which revealed also that mucin and electrolytes influence each other. They found that in the acid medium the gastric mucin does not influence the ferments or absorb them. In water mucin swells into a viscous mass, and in an acid medium the viscosity values are higher than in the neutral medium. This observation contradicts that of another investigator, but the authors think that this is explained by the fact that gastric mucus contains a number of electrolytes, which influence the viscosity, and that the mucin they used had been purified by electroanalysis. In further studies they investigated whether there is a relationship between the quantity of hydrochloric acid and of mucus in the stomach and found that the production of mucin increases as the digestion advances. They propose a theory explaining how the mucin, the hydrochloric acid and the ferments act in the process of digestion. They conclude that the mucin has a number of protective and regulatory functions in the action of the hydrochloric acid and of the ferments which are independent of nervous modifications.

Early Diagnosis of Syphilis—Schreus emphasizes that in the early diagnosis of syphilis the clinical manifestations do not play the important part that is frequently ascribed to them. In spite of the fact that the experienced observer can diagnose a syphilitic infection with a considerable degree of certainty from the typical clinical signs these are not sufficient for a definite diagnosis and alone, do not justify antisyphilitic treatment. It is necessary to demonstrate the spirochetes because disturbances of a nonsyphilitic character may present quite similar symptoms, and the diagnosis of syphilis is of such vital importance for the patient that it cannot be made with too much care. The author stresses that it is a grave mistake to institute arsphenamine therapy merely because a suspected lesion is present and then to diagnose it as syphilitic if it heals in the course of the arsphenamine treatment because a harmless pyoderma, a progonital herpes or simple balanitis may be diagnosed as syphilitic and subsequent clarification of the case is impossible. The author thinks that, if the demonstration of spirochetes should prove impossible, it would be less harmful to wait for the serologic reactions to become positive. In evaluating the three methods of demonstration of the spirochetes of syphilis (demonstration in the dark field the staining method and animal experimentation) he points out that the latter has no practical significance and that the staining method has considerable shortcomings, at any rate as far as the general practitioner is concerned. He considers the dark field method the most suitable one. He describes the preparation of the specimens and the differentiation of *Spirochaeta pallida* from other spirochetes. In discussing the serologic tests the author emphasizes that the weakly positive outcome of the one or the other reaction is not sufficient proof for a definite diagnosis. Cases in which infection is suspected make a prolonged serologic control necessary.

Mechanism of Blood Pressure—Korschegg points out that the different theories of the development of arterial hypertension avoid a consideration of the suprarenals in spite of the fact that it is well known that the suprarenals are absolutely necessary for the maintenance of the normal pressure. It has been the author's aim for several years to find a hormone basis of the blood pressure. His studies have convinced him that the largest portion of epinephrine that is demonstrated in the suprarenals is not present in them under physiologic conditions but is artificially produced by the chemical method used for its extraction. However further studies revealed that the suprarenals contain a substance with vasoconstrictive properties and it was assumed that the substance is a lipid combined epinephrine. It is readily possible to split epinephrine off from this substance, though its efficacy is greatly reduced by this process. On the other hand, it was demonstrated on vascular tissue that the addition of lipid to epinephrine greatly increases its efficacy. The author further demonstrated the presence of this substance in the blood and showed on surviving intestine from a rabbit that the alcoholic blood extract has a tonicizing effect. In later experiments he succeeded in perfecting a colorimetric method for the quantitative determination of an oxidized form of the epinephrine that is split off from the lipid combined vasoconstrictive substance. This method revealed that the values are largely equivalent in normal blood pressure but much higher in hypertension, and it was even possible to determine within certain limits the degree of the hypertension.

Fluorescence in Cerebrospinal Fluid—Plaut and his collaborators found that small quantities of urobilin, which do not fluoresce in aqueous solutions, show a vivid green fluorescence when added to cerebrospinal fluid. The intensity of fluorescence of urobilin produced by the cerebrospinal fluid is of the same intensity as that produced by zinc salt solution, and normal and pathologic cerebrospinal fluids produce the same effect. The action is not dependent on the minerals contained in the cerebrospinal fluid but rather on the colloidal constituents, particularly the colloids belonging to the globulin-free fraction.

Cerebral Changes Following Injection of Soap Solutions into Uterus—Kornyei relates the history of a woman aged 40, who lost consciousness following injection of soap solution into the uterus. Later there developed general tonic spasms with recurrent clonic spasms. Death followed about twenty hours after the woman had introduced the soap suds for the purpose of inducing an abortion. The necropsy disclosed no signs indicating an air embolism in the right side of the heart. Microscopic examination of the brain revealed numerous pale areas and absence of inflammatory changes. The pathologic changes correspond to an extensive impairment of the cerebral cortex as it is observed in severe disturbances caused by vas-

cular changes Since there was no possibility for a paradoxical embolism, the acute appearance and the persistence of a cerebral anemia can be explained by the assumption of a change in the blood caused by an admixture of soap This indicates for the treatment the necessity of the transfusion of a large amount of blood However, even this measure may be expected to be successful only when it is done soon after the injection of a soap solution Since the changes observed in this case have been observed also in other disturbances of pregnancy, which concur with convulsions (eclampsia, uremia), they cannot be considered proof of a criminal abortion

Variety of Babinski's Great Toe Phenomenon—Stefan points out that Babinski's great toe reflex is an abnormal cutaneous reflex and indicates the interruption of the pyramidal tract at some point An extensive literature shows that the reflexogenic zone for the hyperextension of the great toe is not limited to the region of the sole of the foot Babinski elicited the reflex by stimulating the lateral edge of the foot, while other authors showed that it could be elicited by the stimulation of other regions Gerhartz in his studies on spastic reflexes differentiated two groups, those due to cortical disturbances and those due to pyramidal disorders Later Gerhartz described an isolated reflex in spastic conditions, was able to show in postmortem examinations that the pertaining reflex center is in the cerebral cortex on the contralateral side of the body, and was convinced that this was a cortical spastic reflex The author is able to corroborate these statements at least in part He states that the isolated cortical spastic reflex described by Gerhartz may appear isolated but also in other forms He thinks that it is not entirely clear as yet whether the reflex is purely cortical He is inclined to believe that this great toe phenomenon is likewise a variation of the Babinski reflex, the reflex zone of which is localized in the adductor region on the inner side of the thigh Another form of elicibility of Babinski's great toe phenomenon is the symptom of Weil-Edelmann It had been pointed out by Edelmann in former years that Babinski's phenomenon may be elicited if the leg that is extended at the knee joint is being bent at the hip joint The author observed the Weil-Edelmann sign, in addition to Kernig's symptom, in a case of tuberculous meningitis The significance of the Weil-Edelmann sign in meningeal inflammations has been pointed out also by other investigators It may be elicited during the beginning stages of meningitic processes and occasionally even when Kernig's phenomenon is absent

Emaciation of Cerebral Origin—Stefan describes cases of cerebral emaciation that developed after encephalitis after manganese poisoning or in dementia paralytica He calls attention to the rarity of this disorder and to certain interesting secondary manifestations, reviews the literature and discusses the microscopic changes He believes that the condition may be the result of severe damage to sympathetic centers in the interbrain but that the exact localization is as yet impossible.

Cicatricial Carcinoma—Büngeler relates the history of a man, aged 43, who, while welding a copper tube, sustained a burn the size of a half dollar (30 mm) on the dorsal side of the right wrist joint The patient did not ask medical aid for the treatment of this burn but merely covered it with oil and several hours later washed it and applied a dry bandage The wound healed slowly in about four weeks but repeatedly opened again at the edges and bled slightly Since adhesive tape was not available, he applied black insulating tape directly onto the scar of the burn Gradually there developed at the edge of the wound a small nodule The patient was in the habit of bandaging it securely He removed the insulating tape after working hours and removed the black color of the skin by means of benzine About four months after the burn he consulted a physician The growth, the size of a bean, was removed and the wound healed within ten days The physician sent it in for histologic examination, which disclosed a squamous-cell epithelioma The histologic picture resembled greatly that of an experimental tar carcinoma Since the insulating tape contains a certain amount of tar, the author assumes that the use of this tape was the cause of the rapid development of the growth By cleaning and thus defatting the skin with benzine, the patient produced unwittingly all the requirements for the development of an experimental tar carcinoma

*Does Presence of Diphtheria Bacilli in Nose and Auditory Meatus Involve Danger of Infection for Surroundings of Bacillary Carriers? T Hunermann.—p 1661

Erythrocytometry in Anemia—Bock calls attention to the so-called diffraction micrometry introduced by Piper for the measurement of erythrocytes and describes observations he made with a simplified apparatus in patients with pernicious anemia, hepatic disturbances, gastric carcinoma and certain forms of achylia, and also in those who have had severe hemorrhages and in cases of macrocytosis of the bone marrow Erythrocytometry is helpful in the diagnosis and in the treatment of pernicious anemia The mean diameter of erythrocytes in all cases of untreated pernicious anemia is in excess of 8 microns, the mean being 8.35 microns In addition to the enlargement of the diameter, there is a definite broadening and a certain vagueness of the diffraction pictures as manifestation of anisocytosis and poikilocytosis This anisomegalocytosis differentiates pernicious anemia diffractometrically from other forms of anemia Piper's diffraction micrometry is also a simple, most reliable and highly sensitive method for supervising the therapy Remission obtained by liver therapy is indicated by a progressive reduction in the diameter and by

a decrease in the anisopoikilocytosis. The aim of the treatment has not been accomplished unless complete normalization of the distribution picture has been effected. Intensive liver therapy must be continued until the diameter has been reduced below 775 microns. Relapses become manifest in renewed enlargement of the mean diameter. Erythrocytometric studies in liver diseases convinced the author that enlargement of the mean diameter to macrocytic values of more than 765 microns indicates parenchymal impairment. The macrocytosis of liver disease has a mean diameter of 795 microns. In spite of the fact that in certain splilic liver disturbances diameters may be measured that correspond to those of pernicious anemia it is nevertheless possible to differentiate them by erythrocytometry from untreated cases of pernicious anemia. Anisocytosis, which becomes manifest in the width of the spectral rings, is unusually rare, and poikilocytosis, which manifests itself in the vagueness of the colored corona, is entirely absent in hepatic disease. In anemia that develops in carcinoma of the stomach, there exists, in approximately one half of the cases, an anisomacrocytosis of between 765 microns and 83 microns (mean diameter 794 microns) as soon as the hemoglobin content goes below 60 per cent. This type of macrocytosis has significance in the diagnosis of gastric carcinoma. Gastric achylia that exist for several years may cause macrocytosis. After severe hemorrhages there may exist in anisomacrocytosis with approximately the same median diameter as that of "gastric macrocytosis." This phenomenon is of only short duration, but its existence indicates that blood transfusion is advisable. The macrocytoses of the bone marrow are as yet of but slight diagnostic significance, they are found in systemic diseases of the hematopoietic apparatus and in cases with metastases of the bone marrow.

Diphtheria Bacilli in Nose or Auditory Meatus—Hünemann states that diphtheria bacilli, which frequently are virulent, may generally be demonstrated in the nasal secretion of patients with atrophic rhinitis, ozena or dry mucous membranes with crust formation. The same observation may be made on patients with chronic eczema of the auditory meatus. However, clinical observations indicate that these patients do not present a source of infection for their surroundings, and thus it is not necessary to submit them to the same strict regulations that are applied to those diphtheria bacillus carriers who recently have suffered from acute diphtheria.

Polypous Nonulcerated Gastric Tuberculosis J. C. Knoflach and R. Pape—p 1288

*Primary Oliguria E. Lauda—p 1290

Treatment of Asthma L. Hallós—p 1294

Fat Content of Blood and Pathogenesis of Obesity—Raab summarizes his studies on the fat content of the blood of obese persons as follows. 1 The fat content of the blood of obese persons (while the stomach is empty) shows no marked deviation from the norm. 2 The alimentary lipemic curve, following an oil tolerance test increases in the majority of obese persons slightly less than in normal persons. 3 The considerable reduction or complete abolition of the oil tolerance curve, which is noticeable in normal persons following the administration of the blood-fat-reducing hypophyseal hormone (lipotrin), is in obese persons either entirely absent or hardly at all noticeable. 4 Since in the animal experiment the lipotrin effect is absent after the surgical as well as after the pharmacologic exclusion of the diencephalic metabolic center (tuber cinereum), it seems justifiable to assume that a lack of the lipotrin action (determined on the basis of the oil tolerance curve) indicates a reduced reactivity of the diencephalic "fat center" in human obesity. Moreover, it is known that insufficient collaboration of the hypophyseodiencephalic system leads to the formation of deposits of fat in the periphery. 5 In cases of postencephalitic obesity, in diencephalic tumors and so on, the absence of the lipotrin effect is more or less self evident, in cases in which there exist no signs of an organic lesion of

the tuber cinereum, the lack of the lipotrin action may be interpreted as being caused by a lack of reactivity on the part of the "fat center." 6 The resistance to lipotrin in many cases of obesity and the lack of an action in lipotrin, which would mobilize the fat in the peripheral depots, explain the failure of hypophyseal hormone therapy in obesity.

Primary Oliguria—Lauda reports the history of a patient with primary oliguria, which seems to contradict the usual classification of oliguria. On a normal diet, the patient exhibited oliguria. During various periods of the metabolic experiment, on elimination and retention of additional quantities of sodium chloride or of water, he showed a widely differing behavior. At times there was normal or even supernormal sodium chloride elimination and normal water concentration, at other times the addition of salt was excreted normally, but there was a maximal retention of water, then again there was a disturbance that became manifest in retention of sodium chloride. It was demonstrated again and again that the outcome of the water test depended on the phase of the sodium chloride metabolism. Repeated tests revealed that the patient had a primary oliguria caused by sodium chloride retention. The author emphasizes that, if tests are made on such patients without knowledge of the preceding dietetic period, the examiner may obtain at first one and then another result. Thus it would be possible to diagnose the same condition sometimes as constitutional renal oliguria and at other times as oliguria caused by water retention. The author thinks that in the so-called combination forms with sodium chloride and water retention it may be suspected that the dominating sodium chloride retention has not been correctly recognized. There is definite proof only for the existence of oliguria caused by oligodipsia and for oliguria caused by sodium chloride retention. The latter type may be subdivided into three groups: those in which sodium chloride is retained in large quantities so that edemas develop, those which lead to hydrolipomatosis or to sodium chloride-water obesity respectively, and finally those, like the reported case in which there exists only a certain torpidity in the reactivity of the tissues or of a certain center toward a greater sodium chloride content and in which there exists a temporary sodium chloride retention with consecutive oliguria. In regard to the question of the localization of this disturbance, the author cites Jungmann, who assumed a regulatory disturbance in the interbrain, particularly the hypophysis. In the reported case this localization is likely, because of the presence of hypophyseal symptoms.

Elephantiasis and Pregnancy—Bauereisen says that there are two types of elephantiasis: the tropical form caused by *Filaria sanguinis* Bancrofti and the form occurring in the temperate zone, the etiology of which has not been cleared up as yet. Elephantiasis most frequently involves the lower extremities, but it has been known to involve the arm in case of carcinoma of the breast, and another site of predilection is the external genitalia. The author observed a case of verrucous elephantiasis of the abdomen, which is rather rare. He describes this case. He describes the histories of two women, referred to him for interruption of the pregnancy. He is convinced that elephantiasis does not necessitate an interruption of pregnancy, for the elephantiasis swellings may be influenced favorably by conservative measures. He found that a vegetarian, salt-free diet with restriction of the fluid intake is especially helpful. If the lymphatic stasis becomes exacerbated by a complicating puerperal thrombosis, it appears that pregnancy, delivery and puerperium help to loosen the tissues and improve the circulation. Surgical measures, which were tried in these cases, were of slight value. He maintains that the elephantiasis swellings of the external genitalia which may

make the birth of the fetal head difficult, are no indication for interruption of the pregnancy, because delivery by cesarean section involves almost no danger. He emphasizes that conservative measures should always be tried first. Elevation of the diseased members, massage, diathermy, hot baths, injection of a lysine or of pepsin preparations, mustard poultices, hormone preparations and particularly a vegetarian and salt-free diet may be tried successively or in combination. In severe cases surgical methods will have to be resorted to. He doubts the efficacy of the silk thread method of Handley. The Lanz-Kondoleon operation gives better results. Other surgeons have recommended the implantation of tissues that contain lymph vessels to stimulate the formation of new lymph vessels, but so far without success. Others have recommended throttling of the blood supply by ligation of the main artery. This, however, may lead to gangrene and should be resorted to only if amputation could not be avoided in any event.

Genesis of Hyperemesis of Pregnancy—Von Oettingen advances evidence to the effect that psychic elements are not the primary factors in the pathogenesis of the hyperemesis of pregnancy, but that the primary moment is always an organic element. He admits that the manifestations of these organic disturbances may become exacerbated by psychic factors. He considers waste products of metabolism produced in greater quantity during pregnancy by the organs of the pregnant woman and by the fetus, the primary eliciting agent. A toxicosis develops when the combining capacity of the serum, from overtaking, is no longer adequate and if simultaneously or subsequently it impairs the function of the excreting organs.

Osteitis Deformans in Unusual Localization J. E. Sebulle — p. 5054

Peripheral Nerve Lesions After Carbon Monoxide Poisoning—Kat refers to three cases of peripheral nerve lesions complicating carbon monoxide poisoning. The patients presented deep infiltrations of a cartilaginous consistency in the muscles. Two of them presented marked trophic disturbances. The main theories with regard to this lesion are those assuming (1) a toxic action on the nerve trunks, (2) an asphyxia of the nerve tissue, (3) a toxic action on the blood vessels causing stasis and hemorrhage, and (4) mechanical lesions of the nerves by the abnormal position of the extremities during coma. The author attributes great importance to the infiltrations in the muscular tissue as an explanation of the pathogenesis. In his opinion, hemorrhage and reactive edema of muscles occur as a result of vascular intoxication to which a mechanical factor is added, the nerve lesions are caused by pressure on the nerve trunks or the plexuses in these extremely hard infiltrations. Under this assumption which might be called a primarily toxic, secondarily mechanical theory, the muscular infiltrations are to be regarded as an indispensable condition for the causation of the nerve lesions.

Roentgen Examination of Gastric Mucous Membrane E. de F. Licht — p. 429

*Gastroduodenitis T. Andersen — p. 447

Gastroduodenitis—Andersen concludes from his investigations that manifest hemorrhage in patients suffering from gastroduodenitis does not afford evidence of a complicating ulcer. Apart from the cases of pyloric stenosis definite roentgenologic signs of ulcer do not justify the clinical distinction of patients having such roentgenologic changes from patients who lack the roentgenologic changes but otherwise present the same clinical picture. He would group these cases together under the designation of gastroduodenitis. He states that a retention of six hours is without significance in the diagnosis of gastroduodenitis with or without ulcer; a retention of only twelve hours has a practical value in the clinic.

*Acute Idiopathic Hematoporphyria Case H. E. Nielsen — p. 1133
Diastase Content in Cerebrospinal Fluid O. J. Nielsen — p. 1139

Acute Idiopathic Hematoporphyria—Nielsen's case, in a man aged 35 and previously healthy, resembled an acute intoxication in many respects. There was sudden onset of violent colic-like pain, accompanied by pronounced constipation. After two weeks psychic disturbances appeared, lasting about three weeks. During this time paresis of both upper extremities developed and hematoporphyrin was confirmed in the urine. The patient gradually improved. Considerable atrophy of the musculature of the upper extremities was still present on examination a month after discharge.

Investigation on Capillary Resistance III. No Likelihood of C. Avitumiosis as Etiologic Factor in Gastric Ulcer P. Schultzer — p. 1190
Can Positive Seroreaction in Syphilis Disappear Without Treatment? H. Boas — p. 1197

Physiology of Cancer Cells—Fischer says that tumor cells carry in them the germ of their self destruction. They are so labile that influences which do not affect normal cells cause the tumor cells to react with cell division. On the other hand, they are in a state of chronic destruction incessantly leading to physiologic regeneration. A cancer tumor may really be regarded as tissue in a condition of continuous proliferation through the constant forming of new multiple wounds. Where in the cells the cause of their lability and short lifetime is to be sought is still unknown.

Continued Investigations on Mineral Metabolism IV. Effect of Mineral Preparation Kalfositt K. U. Toverud and G. Toverud — p. 1180

Causes of Unsatisfactory Results of Gastro-Enterostomy—Grevle's material comprises seventy-eight patients, observed for from one to sixteen years, who have answered his questionnaires. Fifty-one are cured. In twenty of the remaining twenty-seven with more or less marked disturbances he made clinical and roentgenologic examinations and presents the results in detail. He finds that the anastomosis lies too far to the left in practically all cases. Except in two instances, emptying occurs by both pylorus and anastomosis. In two cases the acidity is increased, in some it is unchanged, and in half of the cases there is an acidity. A peptic ulcer was revealed in a woman with an acidity. The best results are seen in elder patients and the poorest in patients aged between 15 and 20. There is no evidence that the duration of the disorder influences the results of the operation.

Another Fatal Case of Agranulocytosis After Amidopyrine (Cibalgin) C. Holten H. E. Nielsen and K. Transbøl — p. 1162

Establishment of New Blood Type Characteristic—Andersen found an immune receptor, temporarily designated as X, in about 94 per cent of the persons examined. There is, he says, no relation between the presence of the X receptor and the receptors of the ABO and MN systems. The agglutinin anti-X is apparently formed on injection of human blood corpuscles into rabbits but purification of the agglutinin is not so easily accomplished as that of anti-M and anti-N agglutinins. Although the agglutinin is perhaps often present, it cannot be assumed to disturb the M and N determination, since it is easily removed and appears only in weak concentrations in comparison to the anti-M and anti-N reagents applied in the practice.

EPIDEMIOLOGY OF LEAD POISONING

A J LANZA MD

Assistant Medical Director, Metropolitan Life Insurance Company
NEW YORK

The use of lead is so widespread throughout all civilized countries that lead poisoning continues to be a matter of concern to the physician and the public health official. As new processes are evolved in industry and new materials devised for general consumption, so does lead poisoning continue to appear under new and sometimes strange circumstances. For centuries the origins of lead poisoning, its nature, its varied forms, the action of lead in the body, the treatment and the prevention of lead poisoning have all occupied the men of science and the men of industry and the last word has not yet been spoken.

Lead poisoning may well be thought of as a counterpart of syphilis not only in the variety of its effects on the human system but in the manner in which it may be dormant and unsuspected in the tissues for years, apparently innocuous, until some alteration in the metabolic processes liberates it with unimpured venom. Like syphilis, it is a contributing cause of many a death for which it does not receive its rightful share of the blame.

Lead may gain entrance to the body through the respiratory system by inhalation, through the gastrointestinal system by ingestion, and through the skin. It is doubtful whether skin absorption of inorganic lead compounds ever takes place except when the skin is damaged by inflammation or wound. While cases have been reported due to the application of lead-containing medication to ulcerated or damaged skin, this form of entry is of little practical interest. Organic lead compounds, such as tetra-ethyl lead, will penetrate the skin and their employment is guarded by carefully devised precautions.

Recently Fairhall and Heim¹ published the results of their study of lead weighted silk fabrics and found no evidence of absorption even when the fabric was worn next to the skin and under extreme conditions of activity and perspiration.

Inhalation and ingestion are the two routes by which lead gets into the system and the first is the more important. Most of the industrial exposure arises from dust and fumes that are breathed into the lungs and upper respiratory tract, where absorption and excretion involve entry into the systemic circulation. Lead that

is ingested may be excreted unchanged and, even if absorbed, may be carried to the liver and excreted in the bile.² In the main, industrial poisoning is due to inhalation and nonindustrial poisoning to ingestion, though there are, of course, exceptions.

Water supplies conducted through lead pipes have been an important source of community poisoning. In a study of 102 lead-conducted water supplies in New England, 24 per cent of 253 individuals examined were found to be lead poisoned. This study indicated that the greater the carbon dioxide content of the water, the more readily lead was carried into solution. The authors of this investigation concluded that the daily ingestion of 0.1 mg of lead over a period of eight and one-fourth years caused poisoning.³ In the Bulletin of the United States Public Health Service for July 28, 1932, the statement is made that "No water to be used for drinking purposes should contain the equivalent of one-half part lead per million water." An English study showed that the infant mortality in an area exposed to lead-contaminated water fell from 134 to 56 when the water was treated to prevent the lead going into solution.⁴ Epidemics of lead poisoning from water supplies have been reported from England,⁵ France,⁶ Germany,⁷ and other countries.

Numerous instances have been reported both in this country and in England of lead poisoning due to home fermenting and distilling of wines, beers, ciders and similar beverages in utensils glazed with a lead compound. As with water, the acid content of these beverages causes the trouble, the resultant chemical action liberates the lead from the glaze and it goes into solution in the beverage.⁸

Other interesting and important epidemics of poisoning have occurred from time to time to bear witness to the ubiquity of lead and to the strangeness of the circumstances under which it may manifest itself. A series of cases of lead poisoning was reported from Austria in 1931. Lead was used to counterbalance a grinding wheel in a flour mill, with the result that the flour was impregnated with fine particles of metallic lead, poisoning a number of people.⁹ The use of snuff has been identified with lead poisoning, the source of the lead being the metallic foil in which the snuff is wrapped.¹⁰

¹ Fairhall L T and Heim J W. *J Indust Hyg* 14: 317 (Nov) 1932.

One of the strangest occurrences was lead poisoning in a number of Baltimore families caused by the use of discarded storage battery cases for fuel.¹¹ There were forty cases with several of severe encephalopathy among the children. A similar instance in Nashville, Tenn., involved five families and fourteen children.¹²

One of the most interesting of all the chapters on lead poisoning is that dealing with ocular neuritis among children. In 1897 Dr. Lockhart Gibson of Queensland, Australia, published a paper on this subject, referring to two previous reports in 1892.¹³ Dr. Gibson followed up this subject for forty years, reporting cases and endeavoring to trace the source of infection. The general conclusion was that the Queensland cases were due to lead paint on verandas and railings where the children played.¹⁴ Recently similar cases have been described in this country.¹⁵ In Japan, the use of lead-containing toilet powders has caused widespread lead poisoning in both infants and mothers.¹⁶

It is not possible to describe or even to enumerate, in a paper of this length, all the varied industrial processes in which lead is used and the circumstances wherein lead poisoning may arise. Their number is legion.

Unfortunately, also, there is but little statistical information on the mortality from lead poisoning and none with respect to morbidity. In no year since 1920 have there been as many as 150 cases of death from lead poisoning reported in the registration area of the United States. In 1930 there were 101 cases, in 1931, 111. Half of the 1930 patients were painters.¹⁷ These reports are based on death certificates, and there is no doubt that many cases of lead poisoning are reported as nephritis or other organic diseases, with no mention of the underlying cause. The Joint Occupation Study¹⁸ (a life insurance undertaking) showed, for house painters, on the basis of 61,000 life years, 249 actual deaths from all causes, which was 22 per cent in excess of the expected. This excess was reckoned on the basis of ordinary policyholders, corrected for age groups and sex. Aside from this meager information, there is little worth recording.

The following summary refers to the main classification of industries and processes in which lead is a hazard.

1 Lead mining when lead is in the form of soluble carbonates or other soluble salts. It is doubtful whether any appreciable amount of lead poisoning occurs when the ore is galena (lead sulphide).

2 Lead smelting and refining.

3 Handling and fabrication of metallic lead.

(a) Manufacturing of lead articles of all kinds (poisoning due to formation of lead oxide on surface of metallic lead).

(b) Handling metallic lead in hot processes, lead burning, soldering, lead tempering, plumbing.

(c) Brass and other founding in which lead is used.

(d) Buffing and polishing metallic surfaces in which lead is an ingredient.

4 Manufacture of lead salts and compounds, especially lead oxide by Dutch method, Carter method, and other methods, lead pigments, organic lead compounds.

5 Manufacturing processes in which lead compounds are used. These are extremely numerous, among the important ones are the storage battery industry, paint industry, glass industry, rubber compounding and chemical industry.

6 Application and removal of lead-containing paints, enamels and glazes. Painting spray painting vitreous enameling, pottery dipping, sandpapering, scraping and chipping painted surfaces, flame cutting of painted metal, tree spraying with lead containing insecticides.

7 Typographic trades: type founding, electrotyping, stereotyping.

It may be said that in those industries in which lead plays a major part the hazard is fairly well controlled, and it is exceptional nowadays to see cases of acute poisoning with colic and wrist drop in the smelters and establishments where lead oxide, paints and storage batteries are manufactured. There is still in these industries a considerable amount of mild lead poisoning much of which escapes diagnosis because it is mild. Individual carelessness and breaks in the discipline of supervision do occur, and familiarity breeds contempt in the dangerous trades as elsewhere. Much credit, however, is due the lead industries for the perfection of a technique of prevention and supervision, which is, in the main, effective. When one comes across an outbreak of lead poisoning it is usually in an establishment in which a lead process is but one step in the plan of manufacture, as it is under such circumstances that the hazard is apt to be underestimated or ignored. Moreover, it is not uncommon to see lead poisoning among industrial workers not engaged in handling lead but who, through negligence, are exposed to dust or fumes from lead processes not properly isolated or otherwise protected.

Some time ago I had occasion to visit a plant where one process consisted in soldering brass strips. These strips were assembled by girls working at long tables and passed to the man at one end of the table, who did the soldering. The prevailing air currents carried the fumes from the lead pot along the table, affecting the girls, while the solderer escaped any ill effect. Some of these lead poisoning cases will cause the medical Sherlock Holmes to exert his best faculties in detecting the source of contamination. A notable example was contributed by Dr. Leathers of Nashville, Tenn.¹⁹ In this instance, in the vitreous enameling of domestic heaters, a lead-free pigment was used. A number of acute cases of lead poisoning developed, including individuals not associated with the enameling process. It finally developed that there was lead in the glass frit used in making the enamel. As this had not been realized, no precautions were taken. Numerous cases of lead poisoning have been reported due to cutting metal coated with lead paint, with the oxyacetylene flame, especially in the holds of naval vessels and similar confined spaces. Here again the poisoning was not limited to the men actually doing the cutting.²⁰

A great deal of effort has been expended in endeavoring to ascertain the amount of lead present in the atmosphere under varying conditions and the minimum dosage that will cause lead poisoning. Bloomfield²¹ reported that in a number of industrial establishments he found 0.10 mg. of lead to 10 cubic meters of air,

in automobile repair shops 0.13 mg, and in street air, 0.09 mg to 10 cubic meters. Greenburg²² has reported that 1.45 mg of lead daily for two and one-half years has caused poisoning. Teleky²³ states that 1 mg of lead daily for several months and Legge and Goadby²⁴ state that 2 mg daily for several years will cause lead poisoning. While these figures may seem to vary considerably, it is true that lead in the form of vapor is more dangerous than as dust, and the circumstances under which the foregoing estimates were determined were not identical. Certainly it may be concluded that a daily dosage of from 1.5 to 2 mg is distinctly hazardous and eventually will cause poisoning in most, if not all, individuals. In this connection it should be noted that when lead is in a molten condition fumes will be given off, the higher the temperature, the more fumes, also oxide will form on the surface and get into the air as dust.

CONCLUSION

It may be stated that lead poisoning is very prevalent though most of it is mild. However, both mild and occasionally severe cases are commonly not recognized. Many cases are diagnosed as chronic appendicitis and even as gallbladder disease, with all too frequent surgical intervention. In connection with industrial hygiene studies, insurance company records show that, with respect to illnesses of more than seven days' duration among wage earners, respiratory diseases greatly outnumber gastro-intestinal diseases. When the ratio is inverted and one is confronted with a situation wherein the gastro-intestinal cases outnumber the respiratory cases, the possibility of lead poisoning should always be considered.

THE BIOCHEMICAL BEHAVIOR OF LEAD IN THE BODY

JOSEPH C. AUB, M.D.

BOSTON

In the last ten years, a great deal of work has appeared bearing on the biochemistry of lead. To combine this new knowledge with that summarized in a previous publication¹ is my purpose in this article.

In regard to absorption there is little important new evidence. The experience in industry confirms what has been found in the laboratory¹—that lead which is inhaled is far more toxic than lead which is swallowed. Of course, it is likewise generally conceded that ingested lead is a hazard.

The form in which lead is transported in the blood stream is of practical as well as scientific interest, as it has a bearing in guiding intelligent therapy. The prevailing opinion had long been that lead was carried as an albuminate, but Fairhall's equilibrium experiments,¹ as well as our blood studies with Reznikoff,¹ convinced us that lead was precipitated in the bones as the very insoluble tertiary lead phosphate and carried in the blood as the more soluble di-lead phosphate. To

this view Brooks² agreed but Maxwell and Bischoff³ and recently Kehoe and Thamann⁴ have objected, largely on the basis that lead in the blood stream reacts more with red blood cells than does the phosphate. Maxwell and Bischoff³ have produced some evidence that lead, when injected intravenously, is carried as a diphosphoglycerate, while Jowett⁵ thinks that it forms a complex inorganic phosphate with calcium and chlorine. In a chemical system as complicated as blood plasma, an equilibrium of several such chemical compounds is not unreasonable. Any of these compounds might remain ionized and dispersed in the presence of plasma proteins. But whether it is transported as an inorganic or organic phosphate, it is obvious that lead in the blood stream can exert deleterious effects on body cells.

Of course, some absorbed lead is probably excreted (partly in the urine but mostly in the feces) without ever having been stored. There is a growing accumulation of data obtained by different chemical techniques that indicate a small daily lead excretion in the urine in the vast majority of the people in this country and elsewhere.⁶ The average result of these observations indicates a urinary excretion of lead of from 0.05 to 0.1 mg daily in individuals with no unusual lead exposure. This urinary excretion represents lead that has been actually absorbed, but a large percentage of the lead found in the feces has probably never even been absorbed. Because of such repeated observations it must now be agreed that a qualitative demonstration of small quantities of lead in the excreta does not necessarily signify abnormal exposure. According to Barth,⁷ a very small amount of lead may even be gradually accumulated in normal bones during advancing years (from 0.02 mg found in infancy to 0.1 mg per 3 Gm of bone ash in the aged).

If larger quantities of lead are inhaled, swallowed or injected, excretion does not maintain an equilibrium and lead becomes stored. But the extent of possible storage can be ascertained best when a known quantity of lead is injected intravenously. Millet,⁸ Kehoe and Thamann,⁹ and Aub and Smithwick¹⁰ have shown that but little of this is excreted promptly. For example, the average of six of our cases studied for forty-six days during the injection period, showed that only 69 mg of lead was excreted in both the urine and the feces, although 473 mg of lead as colloidal phosphate was injected intravenously.

¹ Aub, J. C., Fairhall, L. T., Minot, Anne S. and Reznikoff, Paul. *Lead Poisoning*. Medicine Monographs. Baltimore: Williams & Wilkins Company, 7, 1926.

Once lead is absorbed, there is a characteristic distribution in tissues, which is approximately the same for inorganic,¹¹ organic¹² or colloidal lead,¹³ no matter what the route of absorption. It is distributed throughout the viscera, but to the greatest extent in the liver, spleen and kidneys immediately following absorption. After a very few days, however, it gradually collects almost entirely in the bones. It is interesting that even a relatively stable organic compound such as tetra-ethyl lead should behave like other lead compounds (Kehoe) in spite of its great solubility in body lipoids.

The crux of the whole problem of lead poisoning, just as for other heavy metals such as radium¹⁴ or mercury,¹⁵ lies in the great avidity with which the bones take up these metals. Circulating lead may cause tissue damage, but lead stored in the bones produces no deleterious effects except probable caries in the teeth. The problem of treating lead poisoning is the problem of controlling the deposit and excretion of lead from this skeletal storehouse.

It was the original contention of Aub and Anne Minot¹ that the direction of the lead stream is similar to that of the calcium stream—that, when calcium is being deposited in the bones, circulating lead is also deposited in the bones, and, when calcium is being pulled from the bones, some stored lead is also liberated.¹

This relationship has been extensively investigated by most laborious metabolic observations. The patients received daily the same diet, similarly prepared throughout their low calcium periods of observation. Their total excretions were collected in three-day periods and analyzed for lead by Fairhall's method. The rate of the lead stream could thus be followed. But the magnitude of this lead stream, it must be remembered, is apt to be relatively small. An adult dying of chronic lead poisoning probably has not more than 1 Gm of lead stored in the entire

Chart 1—The first value indicates the lead excretion as acute lead colic was subsiding during high calcium medication. Later the sustained increase in lead excretion which accompanies a low calcium diet plus ammonium chloride is well shown. The chart shows that the increased excretion is largely fecal.

body, and nearly all of this is in the skeleton. After removal from exposure, such stored lead is normally but slowly excreted. The charts of a few of our unpub-

lished observations are reproduced here to indicate the size of this excretion in cases of lead poisoning while the patients were hospitalized on a rigid, constant, metabolic regimen.^{14a} The first value, determined in chart 1, indicates the rate of lead excretion during the subsidence of an acute lead colic. This chart shows how closely that rate of excretion is again approached during deleading and indicates that the rate of excretion is of a very different order from that ascribed to food and the "normal" lead contacts of daily life. In contrast to this, chart 2 indicates that lead may be pulled from the bones two years after every known exposure has ceased. The large excretion during this first course of deleading indicated that the patient had had a considerable previous exposure and storage.

In these two observations the effect of medication is obvious when superimposed on a diet already low in calcium. But the increase of lead excretion is not invariable. We have had one patient, maintained through a long period on a low calcium diet, in whom the lead excretion was not further increased by adding ammonium chloride, even though the calcium excretion was somewhat accentuated. But the usual result is that increased excretion of bone calcium is accompanied by stored lead.

In our experience, any method that increases calcium excretion also increases the lead excretion. No deleterious effects have resulted since we have learned to apply medication in amounts gradually increased over a period of a week or ten days. The value of these therapeutic suggestions can best be gleaned from the experience of others, and recent reports in the literature in this regard have been predominantly favorable.

The clinical value of high calcium therapy to quiet the toxic episodes of lead intoxication¹⁵ has been confirmed by Badham and Taylor,¹⁶ Belknap,¹⁶ Wiegeldt,¹⁷

Chart 2—Lead excretion in a young man removed from all in dustrial lead exposure for eight months. He had a toxic amblyopia but had received no previous treatment for lead poisoning. The first period indicates the excretion during low calcium diet alone with subsequent addition of ammonium chloride and parathyroid extract-Collip. The recorded units of parathyroid extract were the old units (five times stronger than in the new 1934 nomenclature).

14a. The upper blocks in all charts represent medication expressed in cubic centimeters of molar solution given daily by mouth. The base line of the remainder of the charts is the middle horizontal line marked 0. The chart extends both above and below this line—the farther from this middle base line the higher the value. Above this middle base line is shown the lead excretion expressed as lead excreted by three-day periods. The lighter line is the urinary excretion; the heavier line the total excretion in both urine and feces. Below the middle base line the charts extend downward and indicate the calcium metabolism. The calcium intake is hatched below the base line. When fenced in it indicates a low calcium intake averaging 100 mg of calcium daily. The areas that have no enclosing block lines indicate a diet ample in calcium. The calcium excretion represents the total calcium in both urine and feces by three-day periods.

Leschke¹⁸ and Koyranskiy,¹⁹ and by many in personal communications. It is the type of therapy that can readily be judged by its striking clinical effects. Nothing more dramatic in treatment can be desired than the rapid subsidence of lead colic following the slow intravenous injection of 10 cc of a 20 per cent solution of calcium gluconate. Reduction of lead excretion by a high calcium diet has been confirmed by Litzner, Weyrauch and Barth.²⁰

Increase of the excretions of heavy metals by the liberation of calcium stores has also been extensively studied, and our results were confirmed in one particular or another by many authors. Litzner, Weyrauch and Barth²⁰ confirmed the influence of sodium bicarbonate but were unable to confirm the effect of acidosis. They determined lead excretion only in the urine, and it has been our experience that most of the increased lead excretion appears in the feces. Certainly, urinary lead alone is not an adequate test for total lead excretion. The other publications have shown that acid-producing substances,²¹ parathyroid extract,²² and large doses of viosterol²³ increase the rate of excretion of lead, radium²⁴ and mercury.²⁴ In five cases of lead colic studied with Dr. Marion Ropes, we could determine no influence on lead excretion from daily injections of 1 cc of sodium thiosulphate. This agrees with the negative results on animals of Curtis and Young.²⁵ Shelling²⁶ has also shown by growth curves in rats that phosphate may be important in regulating the deposit of lead. This may well be the case also in children, in whom the normal diet tends to be high in calcium but relatively inadequate in phosphorus. In adults, however, the average diet is low in calcium and the phosphate intake is more than adequate, so that the calcium intake is the easy one to control.

It thus appears that the overwhelming evidence of the past ten years confirms the view that the lead stream and the calcium stream run in the same direction whether these substances are being deposited in the bones or liberated into the blood and into the excreta. To understand this mechanism thoroughly one must turn to the metabolism of bone. It has been demonstrated²⁷ that bone can be considered roughly divisible into two functional elements. The hard cortical bone

acts as the body's support. The trabeculae, scattered through the marrow, particularly at the epiphyses, act as the readily available supply of calcium for body needs. It is this relatively small lace-like trabecular structure, with its large blood supply, which is depleted when calcium is demanded by the body—or refilled when calcium is stored.²⁷ The hard cortex, which constitutes most of the bone with its relatively small blood supply, probably metabolizes at a fairly constant rate. In the trabeculae, lead is stored in relatively high concentration. Thus we²⁸ showed by analyses some years ago, and it has recently been dramatically confirmed by Behrens and Baumann²⁹ by means of their beautiful pictures of radioactive deposits. It is largely the salts in these trabeculae that are liberated in time of calcium need.

However, it is essential to realize that probably not all the calcium and lead that is liberated from this bone is excreted. There is x-ray evidence to indicate that it may circulate and be redeposited in bone, especially in childhood, for the roentgenograms of Vogt³⁰ show that

Chart 3.—Lead excretion determined for three and one-half months in a patient whose acute symptoms of lead poisoning subsided before the observation was started.

the lead gets repeatedly dissolved and redeposited along the epiphyseal line of growth. It is because of this great avidity of growing bone for salts, as well as the difficulties precipitated by calcium deficiencies, that deleading therapy seems an unwise and unsuccessful procedure in children.

The present problem of treating lead poisoning lies not in the methods, for efficient methods exist. The problem that remains to be decided is: Should deleading be undertaken or avoided? If rapid deleading is to be avoided, it is necessary simply to give a large calcium intake in the diet. This lowers the body's demand on calcium stores, so that calcium is even stored, and the only excretion of bone calcium (and lead) comes from the normal metabolism of the bones. Obviously, this is the method that should be used during any toxic lead episode.

But should deleading be undertaken after the episode has subsided? To help in this decision, one must remember that

1 Lead is stored in relatively large quantities in the area of bone readily available for liberation

2 The liberation of this store is an obvious factor in the onset of toxic lead episodes during metabolic upsets

3 This liberated lead may not be excreted but may circulate and be redeposited (No one knows the extent of this possibility)

Therefore, in favor of deleading is the possibility of reducing, under controlled conditions, the lead contamination in the bone trabeculae and then replenishing the trabeculae with uncontaminated calcium. Against deleading is the consideration that it may be desirable to avoid the liberation of lead, which can be kept largely stored in the bones during good health. From the theoretical point of view, deleading seems advantageous in order to avoid sudden liberation of this lead in time of metabolic stress. From the practical point of view the answer is dependent on which procedure will advance most promptly to a recovery of health. In my experience, following the ordinary toxic lead episode, a vigorous course of deleading is usually followed by a prompt recovery to normal health—a recovery that is more rapid and much more complete than when a continued deposit of lead stores is maintained. In lead palsies, I have the impression that thorough deleading approximately halves the period of disability. This opinion, formed from many observations, may possibly be altered, but the biochemical knowledge on which this treatment is based seems to be thoroughly established not only for lead but also for several other related heavy metals.

NORMAL ABSORPTION AND EXCRETION OF LEAD

ROBERT A. KEHOE, M.D.
FREDERICK THAMANN, CH.E.
AND
JACOB CHOLAK, CH.E.
CINCINNATI

A recent series of articles in another journal has detailed the methods and the major results of our studies of lead absorption and lead poisoning during the past ten years.¹ So far as they are concerned with normal lead absorption and excretion, the results may be summarized briefly as follows: 1 Two groups of native Mexican Indians, whose mode of life and environment were devoid of opportunities for contact with the lead-containing products of highly organized and industrialized populations, were found to have lead in their blood and to excrete lead in their feces and urine, as a consequence of the occurrence of lead in the soil and hence in vegetation and animal products employed as food.

From the Kettering Laboratory of Applied Physiology in the University of Cincinnati.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

1 (a) Kehoe, R. A., Thamann, Frederick, and Cholak, Jacob. On the Normal Absorption and Excretion of Lead. I. Lead Absorption and Excretion in Primitive Life. II. Lead Absorption and Excretion in Modern American Life. III. The Sources of Normal Lead Absorption. IV. Lead Absorption and Excretion in Infants and Children. *J. Indust. Hyg.* 15: 257-305 (Sept.) 1933. (b) Lead Absorption and Excretion in Certain Lead Trades. *ibid.* 15: 305-319 (Sept.) 1933. (c) Lead Absorption and Excretion in Relation to the Diagnosis of Lead Poisoning. *ibid.* 15: 320-339 (Sept.) 1933.

2 Various groups of healthy children and adults in the United States, with no occupational exposure, were shown to have lead in their tissues and in their excreta, chiefly because of regular ingestion of lead with their foods. 3 The rate of lead excretion among Americans is higher than that observed in people living under simpler and more natural conditions (native Mexicans), in correspondence with the higher lead content of certain American foodstuffs. 4 Evidence was obtained that the ingestion of these "normal" amounts of lead does not result in steady accumulation of lead in the body. Apparently an equilibrium is reached after a time, so that a substantially constant concentration of lead remains in the tissues, and lead output becomes equivalent to lead intake.

E. C.	0.014 ± 0.001	0.014	0.040 ± 0.002	0.16 ± 0.01

In the course of the work from which these conclusions were derived, certain healthy young men with negative occupational histories were kept under observation for months, during which their lead intake with food and drink (exclusive of water) was measured by analyzing duplicate twenty-four hour food samples and their daily lead output in feces and urine was determined. Nine such subjects have now been included in our observations. The results have yielded a consistent picture of normal lead ingestion and normal lead excretion, as measured by the analytic methods that we have described.^{1a} The results are grouped in tables 1 and 2 in such a manner as to bring out the facts that we wish to introduce as points of departure for the further observations to be described.

NORMAL LEAD INGESTION AND ITS RELATION TO
NORMAL FECAL LEAD EXCRETION

In table 1 all the observations on twenty-four hour food and fecal samples are listed according to the frequency of their occurrence, together with the calculated mean values, their probable errors and their deviations

TABLE 3—Distribution of Results on Medical Students According to Milligrams of Lead per Sample of Feces

Milligrams of Lead per Sample of Feces*	By Chemical Method			By Spectrographic Method
	On Portion Analyzed	On Entire Sample	After Correction for Loss†

Probable error of mean	±0.003	±0.003
Standard deviation	±0.038	±0.034

Three samples lost in process of analysis.

From the similarity of the frequencies and the lack of differentiation of the means for the two sets of samples, the approximate equivalence of lead ingestion and alimentary lead output is apparent. Such difference as exists between the two means, though not statistically significant, suggests that more lead is excreted with the feces than is ingested with the food. From these observations alone we should be justified in suspecting what we have found to be true on other evidence—that the bulk of normal lead is ingested with the food and is passed through the alimentary tract unabsorbed. Doubtless, however, a portion of the ingested lead is absorbed, while some is excreted from the tissues into the alimentary tract, as it is into the urine.

THE MAGNITUDE OF NORMAL LEAD EXCRETION IN
THE URINE AND FECES, AS DETERMINED
BY CHEMICAL ANALYSIS

Table 2 gives the calculated means and their probable errors for eight of the nine subjects, as to the quantities of lead found per liter and for each twenty-four hour

period in the urine, and per gram of ash and for each twenty-four hour period in the feces. (One of the subjects was followed for too short a period to provide statistically satisfactory data.) The respective mean values for the group are in such close agreement (with the exception of those concerned with fecal lead in milligrams per gram of ash²) as to demonstrate a remarkable similarity in the subjects with respect to their lead absorption and excretion.

THE MAGNITUDE OF NORMAL LEAD EXCRETION IN
RELATION TO ANALYTIC METHODS

It is obvious that the accuracy of these figures must depend on the adequacy of the analytic methods. Comparison of these values with those given by other workers must take into account the variable sensitivity of the divergent analytic methods used. All chemical methods that are based on the separation of lead by its insoluble salts from other metals have a common quality in that with proper handling they yield low results. Each method has its own inherent loss, and if such loss is uniform and of known magnitude, each will

TABLE 5—Distribution of Results on Medical Students According to Milligrams of Lead per Liter of Urine

provide data that can be correlated with those given by other standardized methods.

With these considerations in mind we recently employed a spectrographic method to check the uniformity and the magnitude of the loss associated with the routine use of our chemical method. The spectro-

2 The high variability of the individual mean values for lead in milligrams per gram of ash in the feces is sufficient proof that this relationship has little physiologic meaning. It may be employed as a rough expression of the relationship between quantity of lead and size of fecal sample.

graphic method, described elsewhere,³ has been shown to have an accuracy of ± 25 per cent as applied to amounts of lead ranging from 0.00002 to 0.0004 mg (Such amounts within the arc correspond to concentrations of from 0.01 to 0.20 mg of lead per liter of urine.) Parallel estimation of known amounts of lead by the two methods has shown a uniform loss on the part of the chemical method amounting to approximately 0.07 mg per sample. Both methods were employed in carrying out the following study.

NORMAL LEAD IN THE URINE AND FECES, AS DETERMINED BY PARALLEL SPECTROGRAPHIC AND CHEMICAL ANALYSES. NORMAL LEAD IN THE BLOOD

A newly matriculated class of medical students assembled from widely distributed parts of the United States were interviewed and examined. Blood samples (50 cc) were taken, and 3-liter to 4-liter samples of urine and a single fecal evacuation (representing in general a twenty-four hour sample) were obtained. Each sample of urine and feces was examined by both methods.

The data are shown in tables 3, 4 and 5. The results of the chemical analyses are in close agreement with those of the prolonged individual studies recorded in tables 1 and 2. The spectrographic results are significantly higher. That the discrepancy between the two sets of observations was uniform is shown in tables 3 and 5, in that the distribution of results and the calculated mean values for the two are practically identical when each positive chemical result is corrected for loss by the addition of 0.07 mg. (The negative results given by the chemical method could not be dealt with for the obvious reason that they may have contained no lead or any amount up to 0.07 mg.)

The lead content of the blood samples was determined by the spectrographic method alone. The results are grouped according to the frequency of their occurrence in table 6.

ABSOLUTE VALUES FOR NORMAL LEAD INGESTION AND LEAD EXCRETION

The demonstration of the occurrence of a uniform loss of 0.07 mg per sample in our chemical method provides a basis for establishing the actual level of normal lead excretion in the American population, through the correction of results obtained by our chemical method alone. Applying this correction directly to the mean values recorded in table 1, the mean lead content of twenty-four hour samples of food becomes approximately 0.25 mg, and the mean daily fecal output comes to about 0.26 mg. The urinary results in table 2 cannot be corrected directly, but the addition of 0.07 mg to the amounts found per sample and the recalculation of the quantities per liter and per twenty-four hour period result in mean values ranging from 0.06 to 0.08 mg per liter and from 0.05 to 0.10 mg per twenty-four hours. Individual twenty-four hour samples of normal feces may contain 1 mg of lead or even more, while a normal sample of urine may show as much as 0.20 mg per liter rarely and 0.10 mg per liter not uncommonly. Such results, whether due to extremes in physiologic variation or to chance contamination of samples, illustrate the danger associated with the interpretation of any single analytic result. In fact, the differentiation

of a normal individual from one who has been exposed recently to abnormal amounts of lead requires at least the examination of samples of both urine and feces. An additional factor of safety in judgment is provided by an analysis of the blood.

SUMMARY AND CONCLUSIONS

1 The chemical methods for the determination of lead in human excreta and blood which we have used and described yield uniformly low values.

2 Comparison of parallel lead determinations made by spectrographic and chemical methods shows the inherent loss of our chemical method to average 0.07 mg per sample.

3 On the basis of the spectrographic method, or on that of the chemical method corrected for a standard loss of 0.07 mg of lead per sample, the mean lead excretion of a group of medical students amounted to 0.24 mg for each twenty-four hours in the feces and to 0.04 mg per liter in the urine.

4 The mean quantity of lead in the blood of the same group of subjects was 0.06 mg per hundred cubic centimeters, as determined spectrographically.

5 The mean daily lead content of the feces of a group of nine normal subjects as determined by chemical analysis over a period of months amounted to $0.193 \text{ mg} \pm 0.003 \text{ mg}$. Allowing for an average loss of 0.07 mg of lead per sample in analysis, the mean amount of fecal lead excreted daily was approximately 0.26 mg.

6 The mean urinary lead excretion of these individuals determined by chemical analysis ranged from 0.014 mg to 0.029 mg per liter, and from 0.014 to 0.032 mg for each twenty-four hours. After correction for loss, the actual means ranged from 0.06 to 0.08 mg per liter and from 0.05 to 0.10 mg for each twenty-four hours.

7 The source of the lead intake was found largely in the food. Its mean daily lead content as based on chemical analysis was $0.176 \text{ mg} \pm 0.004 \text{ mg}$. When corrected for chemical loss, the mean daily lead intake was approximately 0.25 mg, an amount slightly but not significantly less than the lead output in the feces.

[EDITORIAL NOTE.—The three preceding papers, together with the three papers by Drs. Jones, Belknap and Gray, to appear next week, constitute a symposium on lead poisoning. The discussion will follow the papers to be published in the next issue.]

Paralysis Agitans—It is only twenty-two years ago that the corpus striatum was shown by Kinnier Wilson to be the site of degenerative lesions associated with rigidity and tremor. Paralysis agitans or Parkinson's disease has been known for over a hundred years since his original description in 1817, but it is only of late years that Ramsay Hunt and others have assigned the site of its lesion in the pallidal region of the lenticular nucleus. This has not yet been so conclusively proved as in Wilson's disease, or progressive lenticular degeneration. Wilson demonstrated chronic degeneration in the putamen in several cases of this disease, which may be familial. These cases do not resemble Parkinson's disease at all closely, though the tremors and rigidity recall this disease. Characteristic signs are the spastic smile with mouth fixed open, the meaningless laughter, mental hebetude, and especially the associated atrophic cirrhosis of the liver. Allied to this disease is torsion spasm—a rare form of irregular slow spastic movements of head, trunk, and limbs. This disease differs from athetosis, a sequel of infantile hemiplegia or diplegia, in that in the latter the torsion spasms affect the limbs only.—Harris, Wilfred. Tremor, Ataxy and Spasm. *Lancet* 2:1145 (Nov. 24) 1934.

TUMORS OF THE FRONTAL LOBE

CLINICAL OBSERVATIONS IN A SERIES
VERIFIED MICROSCOPICALLY

HAROLD C VORIS, MD

Fellow in Neurologic Surgery the Mayo Foundation

ALFRED W ADSON, MD

AND

FREDERICK P MOERSCH, MD

ROCHESTER MINN

This study is the result of an analysis of the clinical observations in a series of 314 cases of tumor of the frontal lobe encountered at the Mayo Clinic up to Jan 1, 1933, in which the tumor was verified microscopically. In a previous paper by Voris, Kernohan and Adson,¹ this series was analyzed from the standpoint of the anatomic site, pathologic classification and operability of the tumors. Various anatomic groups were established, for example, that in which the tumor was confined to the frontal lobe, comprising 122 tumors, that in which the tumor was primary in the frontal lobe but invaded other parts of the brain, comprising 152 tumors, and, finally, that in which the tumor originated elsewhere but invaded the frontal lobe secondarily, comprising forty tumors.

In summarizing and tabulating the principal clinical studies in this paper, we will give the relative frequency of occurrence of these growths and will emphasize the predominant symptoms. Special attention will be paid to certain signs and symptoms that universally have been considered to be diagnostic of lesions of the frontal lobe. In addition, the relation of age and sex of the patient to the pathologic type of the tumor will be noted.

Since careful analysis has failed to reveal any significant difference in the clinical manifestations in the anatomic groups previously mentioned, we are presenting the results of analysis of the entire series, thus avoiding the confusion of a separate presentation for each group. However, for purposes of comparison, we have analyzed separately forty-nine of the 122 cases in which the tumor was confined to the frontal lobe, in these forty-nine cases we had information from operation or necropsy as to the exact extent of the tumor. This group of forty-nine cases has still further been divided into three subgroups, depending on the areas, according to Campbell's classification (quoted by Tilney and Riley²) which were involved by the tumor. These subgroups are that in which prefrontal and frontal areas (silent cortex) were involved, comprising thirty-three tumors, that in which premotor and motor areas only (electrically excitable cortex) were involved, comprising three tumors, and that in which some combination of these areas was involved, comprising thirteen tumors. The presentation of the observations in these forty-nine cases in which the region of involvement was definitely known will be made in some of the tables side by side with the observations for the entire series, thus affording opportunity for direct comparison.

In regard to the relation between age and sex of patients in this series and pathologic type of tumor, by far the greatest number of patients, 241, or 77 per cent, were in the fourth, fifth or sixth decades of life. Gibbs,³ in reviewing 262 cases of tumor of the frontal lobe at Cushing's clinic, found that only 65 per cent of his patients were in these decades of life. On the other hand 29 per cent of his patients were more than 60 years old compared to about 4 per cent of ours. There is no very significant difference in the age incidence for any of these types of tumor, although a slightly greater number of patients with endothelioma than of those with glioma were in these three decades of life. There were more men than women in this series, approximately in the ratio of three to two. However, of patients with various types of glioma there were nearly twice as many men as women, whereas of those with endothelioma the sexes were about equally divided (table 1).

When the various types of tumor were arranged according to duration of symptoms from the onset of the initial symptom to the time the patient came to the clinic for attention, it was of particular interest to find that almost half (45 per cent) of the patients with spongioblastoma multiforme in this series had had symptoms referable to an intracranial lesion for more than a year, this was quite contrary to the usually accepted view. Again, taking patients with various types of glioma as a group (194), it will be noted that exactly 50 per cent (ninety-seven) of them had had symptoms of tumor for one year or more before coming to the clinic (table 2).

It should be emphasized that these figures for duration of symptoms are from the onset of the initial symptom that was referable to an intracranial lesion, to the time at which the patient sought relief at the clinic. We believe that such figures, particularly for the group of tumors in question, are valuable for correlation with the microscopic evidences of malignancy and with the so-called survival periods, which have been published by Cushing⁴ and others, that give the average survival periods for the different pathologic groups irrespective of the situation of the tumor, these usually include the survival period after the operation or treatment with roentgen rays.

The duration of life compatible with intracranial tumor depends on at least three factors. The first factor is the life cycle or rapidity of growth of the neoplasm. This is important not only because of the simple time element concerned in growth but also because the intracranial contents can better adjust themselves to slow increase in pressure, hence, slow-growing tumors may exist for a long time and reach relatively great size before giving rise to acute symptoms. The second factor is the situation of the tumor, and this also may be of the greatest importance, for example, a fibrous astrocytoma in the midbrain may, while still of very small size, produce death by blocking the aqueduct of Sylvius and producing internal hydrocephalus. Again, tumors of the brain stem must soon result fatally because of the importance to life of the bulbar or diencephalic centers that become involved early in these cases. On the other hand, tumors may reach great size before causing serious symptoms, especially if situated

above the tentorium. Finally, the third factor is the treatment that is given, namely, the type and extent of surgical procedure and the dose of radiation.

In this paper the factor of treatment is not discussed, since our object is to present clinical observations. Further, in a series of tumors confined to the frontal lobe the factor of situation of the neoplasm, although important, is perhaps less so than it would be for tumors in any other part of the brain. Only rarely do tumors of the frontal lobe produce obstructive hydro-

cephalus (tumors in the median line may do so by occlusion of the foramen of Monro, but this is relatively rare), and moreover this portion of the brain contains a relatively large area of so-called silent cortex. For these reasons we believe that this series of cases gives a good picture of the average duration of symptoms associated with various types of glioma.

The initial complaint is a matter of interest, as often it may be the only symptom for a considerable period of time. In 112 of 312 cases the initial complaint was some type of convulsive seizure. Grand mal was by far the most prevalent type and it occurred as the initial

* In two cases in this series the tumor was found accidentally at necropsy and proved to be an endothelioma confined to the frontal lobe. As these growths had given no objective signs or symptoms they are omitted from the table.

complaint in seventy-five cases, or about 25 per cent of all cases in the series. It was the initial complaint in approximately a fifth of the cases in which the tumor was confined to the prefrontal-frontal area (silent cortex). Jacksonian fits occurred in twenty-nine cases and petit mal in eight as the initial complaint. Headache was the next most common initial complaint, occurring in eighty-five cases, or 27 per cent of the cases in the series. Mental change of some type was the next most common initial complaint, occurring in thirty-one cases, or 10 per cent of the cases in the series.

Although failing vision was the initial complaint in only twenty-five cases, 8 per cent of those in this series,

it was the initial complaint in 13 per cent of the cases in which the tumor was confined to the prefrontal-frontal area, the large number of basofrontal endotheliomas (eleven) in the latter group accounts for this increased frequency. The only other initial complaints occurring with greater frequency than in 3 per cent of all cases in this series are those of hemiparesis, which occurred in thirteen cases, and of extracranial swelling, which occurred in ten. The initial complaint in the remaining cases was as follows: general debility in five cases, dizziness in five, syncope in four, loss of sense of smell in four, paresthesia in four, drowsiness in three, aphasia in three, ataxia in three, vomiting in two, and stiff neck, insomnia and uncinat fits in one each.

When one comes to consider the various complaints from which each patient suffered, one finds a little different picture. Headache was the most common complaint in all groups except those in which the tumor was confined to the premotor or motor areas or to a

TABLE 3—*Various Complaints in 314 Cases of Verified Tumors of the Frontal Lobe*

Hemiparesis	111 (35%)	3 (9%)	2	4	9
Total	314	33	3	13	49

combination of prefrontal and premotor areas, in the first instance some form of convulsion outranked headache in frequency and, in the second, both convulsive attacks and mental change outranked headache. Headache was present in 83 per cent of cases in the entire series and in about the same percentage of cases in which the tumor was confined to the prefrontal-frontal areas (table 3).

Convulsive attacks ranked next in frequency, occurring in 69 per cent of all cases and in 55 per cent of cases in which the tumor was confined to the prefrontal-frontal area. In the latter group, however, they stand next to last in order of frequency, being outranked by mental change, by visual disturbances, and by nausea and vomiting. It should be stated that the total for all forms of epileptiform attack is somewhat misleading, as some cases are counted twice since they presented various combinations of grand mal, focal convulsions and petit mal. Thus, in cases in which the tumor was known to involve premotor or motor areas or some combination of these areas with frontal and prefrontal areas, the total of the various forms of epileptiform

attack exceeds the total number of crises in the group. Grand mal alone was present in about 40 per cent of all crises in the series. Parker,⁵ in a previous study at the clinic of convulsions in brain tumor found that 52 per cent of a series of fifty patients with tumor of the frontal lobe suffered from convulsive attacks. The side involved by the tumor among patients suffering from grand mal is of interest. In the entire series 123 patients suffered from attacks of grand mal before coming to the clinic, 46 per cent of these had left-sided tumors, 33 per cent right-sided tumors, and 21 per cent bilateral tumors. Of the 314 tumors, 40 per cent were on the left side, 36 per cent on the right and 24 per cent were bilateral. Thus, there is a slight, but not very significant, preponderance of involvement of the left side among patients suffering from generalized convulsions. Jacksonian attacks or focal convulsions were less prevalent than grand mal, except in the three cases in which the tumor was known to be confined to the premotor-motor area. All three of these patients had Jacksonian attacks of the contralateral side and one had grand mal in addition. Petit mal occurred still less frequently.

Mental change was the next most frequent complaint. These mental phenomena will be discussed in connection with the results in examinations of patients in the series. It should be emphasized that the figures in table 3 represent those cases in which some type of mental change was complained of either by the patient or by those accompanying him at the time he first came to the clinic. Sixty-three per cent of all cases presented this complaint, as did about the same percentage of those in which the tumor was known to be confined to the prefrontal-frontal area.

Nausea and vomiting ranked next in importance in the entire series, being far outranked by headache (as Frazier and Gardner⁶ found) with which it is usually bracketed in discussions of the symptoms of brain tumor. Nausea and vomiting were present in 50 per cent of all cases and in 58 per cent of those in which the tumor was known to be confined to the prefrontal-frontal area. Gibbs³ analyzed his cases for projectile vomiting and found it present in 10 per cent of the cases of tumor of the frontal lobe. Like Kolodny,⁷ we found projectile vomiting rare, and when it had been present it had usually occurred on only one or two occasions and had been associated with more frequent vomiting of the usual type.

Visual disturbance, of some sort, was present in 43 per cent of all cases and in 67 per cent of those in which the tumor was known to involve only the prefrontal-frontal area. Again the large number of basofrontal endothelomas in this group probably accounts in part for this increase in the latter figure over that for the entire series. For example, eleven of the thirty-three patients with prefrontal-frontal tumors had basofrontal endothelomas (all with visual disturbance), these being left out of account, half of the rest still had some visual complaint.

The subject of weakness or paralysis of the contralateral side of the face, or of the extremities will be discussed under observations at examination. On

admission to the clinic, 35 per cent of the patients in the entire series complained of some weakness of the contralateral side of the face or extremities, but a similar complaint was made in only 9 per cent of cases in which the growth was known to involve the prefrontal-frontal area alone.

The most frequent change found at examination of patients in the series, exclusive of mental changes was some degree of choking of the optic disks, from 1 diopter to a maximum of 7 or 8 diopters. It occurred in 62 per cent of all cases and in 79 per cent of those in which the neoplasm was confined to the prefrontal and frontal areas alone. Gibbs, in his large series, tabulated only cases in which choking of disks

TABLE 4—Results of Examination in 314 Cases of Verified Tumor of the Frontal Lobe

Nystagmus	40 (13%)	4	1	2		7
Total	314	33	3	13		49

amounted to 4 diopters or more, the total of such cases was 28 per cent of his series, a surprisingly high figure considering the high degree of choking of the disk (table 4).

Reflex disturbances on the contralateral side, either increase in tendon reflexes or decrease in cutaneous reflexes, or the presence of such pathologic reflexes as Hoffmann's, Babinski's or Rossolimo's, were the next most important changes from the standpoint of frequency. They were present in 58 per cent of cases of the entire series and in 45 per cent of those in which the tumor was known to involve only the prefrontal-frontal area. As might be expected, such reflex disturbances were present in about three-fourths of the cases in which tumors were confined, in part at least, to the premotor or motor areas.

It is of interest to contrast the figures for some degree of weakness of the contralateral extremities with those for contralateral central weakness of the facial

⁷ Kolodny Anatole. Symptomatology of Tumor of the Frontal Lobe. Arch. Neurol. & Psychiat. 21: 1107-1127 (May) 1929.

muscles, since Sachs⁸ and others have emphasized this as an important diagnostic sign in tumor of the frontal lobe. There is no significant difference between the two in cases in which the tumor was known to be confined to the prefrontal and frontal areas. For the whole series, hemiparesis ranks slightly higher in order of frequency. In a few cases of the series there was homolateral weakness of the extremities. Kernohan and Woltman⁹ have discussed the homolateral pyramidal signs in brain tumor and given the probable anatomic explanation.

Perimetric field defects were present in 32 per cent of cases in the entire series and in almost half those in which the growth was confined to the prefrontal-frontal area. Two factors must be taken into account with these figures. 1 Many patients are not able to cooperate sufficiently for perimetric examination, so doubtless the figures all are too low. This criticism may be applied, of course, to any of the changes listed, although to a much greater extent to field defects than to such conditions as choked disks, reflex disturbances, palsies and so forth, which can be elicited with little or no cooperation on the part of the patient. 2 The number of basofrontal tumors present again increases the figures for tumors confined to the prefrontal-frontal area. Thus, if such basofrontal tumors are left out of account, six of the twenty-two patients, or 27 per cent, suffered from some type of perimetric field defect, a radically different figure from that just given.

Under the heading cerebellar signs, we have included the manifestations of ataxia and incoordination and adiadokinesis of the homolateral extremities. One or more of these signs was present in 32 per cent of all cases and in about the same percentage of those in which the tumor was confined to the prefrontal-frontal area. Hare¹⁰ reviewed a series of fifty cases of tumor of the frontal lobe with reference to cerebellar signs, and he found that 10 per cent presented marked cerebellar signs and 40 per cent showed few or vague signs. The lesion was bilateral or in the median line in three of the cases with marked cerebellar signs and probably in a similar situation in the other two. Gordon¹¹ recently reported five cases of unilateral tumor of the frontal lobe with cerebellar manifestations. In a previous paper, Voris, Kernohan and Adson referred to the probable anatomic explanation of the cerebellar phenomena of tumors of the frontal lobe and pointed out the importance, in this regard, of the thalamo-frontal sensory connections, described by Poliak.¹² A certain small proportion (probably about 10 per cent) of tumors of the frontal lobe are very difficult to distinguish clinically from lesions of the posterior fossa and probably they will always require the aid of ventriculography in arriving at a final diagnosis.

Disturbance in speech of some degree was present in 29 per cent of cases in the entire series and in 15 per cent of those in which the neoplasm was confined to the prefrontal-frontal area. Of the ninety-one cases presenting some disturbance in speech, in 65 per cent the tumor was on the left side, in 19 per cent on the right side, and in 16 per cent it was bilateral. Aside

from the possibility of contralateral pressure on the motor speech centers or on their efferent fiber tracts, the question naturally arises in what proportion of the seventeen cases of aphasia with right-sided tumors the patients were left handed. Unfortunately, our records are not adequate on this point. An additional possibility is present, namely, that, in some cases in which persons are right handed but have a hereditary tendency toward left-handedness, the motor speech centers may be situated on the right side in spite of the dominance of the left hand center.

External ocular palsies, usually of the external rectus muscle but occasionally of muscles innervated by the oculomotor or trochlear nerves, were present in about a fifth of the cases in the entire series and in a little more than a fourth of those in which the tumor was confined to the prefrontal-frontal area. Sphincteric disturbances, often considered a part of the classic picture of tumor of the frontal lobe, were present in 20 per cent of all cases, and sensory disturbances on the contralateral side of the body in 15 per cent. Only one case, in which the growth was confined to the prefrontal-frontal areas, presented sensory disturbances.

Under the heading of special signs we have included such conditions as reflex or so-called forced grasping, apraxia, deviation of the head or eye, and perseveration or retardation of motor movements. Adie and Critchley,¹³ in 1927, collected from the literature twenty-two cases of forced grasping and groping associated with lesions of the frontal lobe and added three cases of their own. Since that time, the phenomenon has received considerable attention from physiologists. Fulton and others¹⁴ have produced it experimentally by producing lesions of the contralateral premotor area (area 6 of Brodmann). Kennard and Fulton¹⁵ recently concluded from similar experiments with primates that spasticity and reflex grasping associated with Babinski and Rossolimo signs pointed to a lesion of the premotor area or of its projection system. The relative parts played by lesions of the premotor and motor cortex in producing spasticity seen clinically in man has not entirely been settled. The signs referred to appeared singly or in combination in 15 per cent of the cases in the entire series, in 6 per cent of those in which the tumor was confined to the prefrontal-frontal area, and in 19 per cent of those in which the premotor or motor areas were to some extent involved.

Nystagmus may be considered a cerebellar or vestibular sign. However, an electrically excitable center for ocular movements is known to exist in the posterior part of the middle frontal convolution. Fox¹⁶ has studied the disorders of optic nystagmus in lesions of the frontal lobe and concludes that, when disorders are present, they are elicited when visual objects are moving in a direction toward the side of the lesion. At any rate, we have listed nystagmus as a separate manifestation. It occurred in 13 per cent of all cases and in practically the same percentage of those in which the growth involved only the prefrontal and frontal areas.

The mental phenomena encountered in cases of intracranial tumor, particularly in those of tumor of the

frontal lobe, have always attracted a great deal of interest. The literature on the subject is rather voluminous and is difficult to review critically because of the different terminologies and points of view of the various writers and because, in many of the larger series reported cases have been collected from the literature, making, it seems to us, for a great deal of

error both as to anatomic localization of the tumor and as to interpretation of the mental phenomena.

Some of the more important papers are those of Baruk,¹⁷ Giannelli,¹⁸ Muller,¹⁹ Schuster²⁰ and Vincent.²¹ The monograph of Baruk is one of the most valuable. After a clear exposition of the difficulty of coordinating cases from the literature and of attempts to base psychic disturbances on localization, he divided the mental symptoms of tumors of the frontal lobe into three classes (1) mental impairment, (2) changes of character and emotion, and (3) changes of spatial orientation. He reported only ten personal cases of tumor of the frontal lobe in which mental symptoms were present. Giannelli reported six personal cases, all presenting mental changes, and collected 165 cases from the literature with mental symptoms in 69 per cent. Schuster made an elaborate report of 147 cases of tumor of the frontal lobe with mental symptoms, all his cases, however, were from the literature, thus laying his report open to the criticism previously mentioned.

Our records have primarily been made from the standpoint of clinical neurology and not from that of psychiatry. This insures that the figures given in most

cases represent well marked phenomena and in all probability they are too low. This, too, may account for the relatively higher percentage of such phenomena as loss of memory and indifference to environment, contrasted with more imponderable phenomena such as disorders of humor or character. With these reservations table 5 is presented.

In addition to the 198 patients with a complaint of mental change, the results of examination indicated that twenty-one more presented objective evidence of mental abnormality. Thus 219 patients, or 70 per cent, exhibited some mental abnormality, as did the same percentage of those with tumors in the prefrontal-frontal area. Thus mental abnormality was the most common manifestation except in the small group in which the areas involved were known. It equals choked disks in frequency (table 4) but was exceeded by the latter in cases in which prefrontal and frontal areas were involved, it was not found at all in the cases in which the premotor and motor areas were involved (table 5). Considerable attention has been paid in the literature to the question of the dominance of the left frontal lobe in the psychic life of the individual, and a good deal of conflicting clinical evidence has been presented. Taking the series as a whole, lesions associated with mental changes were on the left side in 40 per cent of the cases, on the right side in 34 per cent, and bilateral in 26 per cent. These figures correspond almost exactly to the percentages previously given for the situation of tumors of the entire series, namely, left side 40 per cent, right side 36 per cent, and bilateral 24 per cent. The total figures are greater than those previously reported by one of us,²² who found that 40 per cent of 116 patients with tumor of the frontal lobe showed mental signs.

Indifference to environment was the most frequent mental symptom (table 5). Next in order of frequency was loss of memory and, following that, some type of change in personality or in character. We would especially call attention to the question of orientation as to time and place. Marie and Behague²³ considered disorientation in space to be a definite syndrome associated with lesions of the frontal lobe. We have not found it so, the total for all groups for dis-

TABLE 6—Roentgenographic Evidence of Tumor in 314 Cases

	Total Evidence*	Direct Evidence*	Indirect Evidence*
All tumors	314	39 (12%)	65 (21%)
Endotheliomas	109	31 (28%)	82 (29%)
Oligodendrogliomas and oligodendroblastomas	25	4 (16%)	10 (36%)

* Direct evidence includes proliferation or erosion or both of bone over an underlying tumor, or visualization of calcium deposits in a tumor.

† Indirect evidence includes evidences of increased intracranial pressure such as thinning or pressure erosion of the bones of the calvarium and erosion of the sella turcica and of the clinoid processes.

orientation in time and place were the same, so that we have not listed them separately. In addition, we found few patients showing one phase of disorientation without the other. The phenomenon of disorientation was encountered in only 15 per cent of cases in the entire series and in a slightly smaller proportion of cases in which the tumor involved only the prefrontal and frontal areas. Changes in character and in emotion,

such as witzelsucht, euphoria, moria and puerility, were even less frequent, occurring in 11 per cent of all cases but in only 6 per cent of those in which the growth was known to be confined to the prefrontal-frontal area

The conclusion is inevitable, we believe, that, whereas spatial disorientation or changes in character or in emotion may be valuable diagnostic signs when present, their absence is small assurance that a lesion of the frontal lobe does not exist

With increasing technical skill in making roentgenograms of the skull and with increasing knowledge of their interpretation, the roentgenologic examination of the head has become more and more important in the diagnosis of intracranial lesions. For this reason it is of interest to tabulate the results of roentgen examinations in this series of tumors. Table 6 gives the roentgenographic evidence, both direct and indirect, for the entire series. In addition, it is given for the two groups of tumors, endotheliomas, and oligodendrogliomas and oligodendroblastomas, for which it is traditionally the most useful. In the entire series, there was roentgenographic evidence pointing to the presence of an intracranial tumor in 124 cases, or about 40 per cent. The ratio of direct to indirect evidence was a little less than 1 to 2

Of the 109 patients with endothelioma, sixty-three or 58 per cent gave roentgenographic evidence of an intracranial lesion, with a practically equal division between the direct and indirect classes of evidence. Of the twenty-eight patients with oligodendroglioma or oligodendroblastoma, fourteen gave roentgenographic evidence of the lesion, ten indirect and four direct. It should be noted that for these two classes of tumor roentgenographic evidence of an intracranial lesion was given in 62 per cent of the 124 cases in the entire series and in 90 per cent of the thirty-nine cases with direct evidence of such a lesion

SUMMARY

The clinical observations have been tabulated for a series of 314 cases of tumors of the frontal lobe microscopically verified, these cases had previously been classified as to anatomic site and pathologic classification of the lesion. The age and sex of the patients are given for each pathologic type of tumor. The duration of symptoms before patients came to the clinic is considered in relation to the type of tumor present

The initial complaint in each patient's history is considered in relation to the various anatomic groups of tumors, as also are the principal complaints from the standpoint of frequency, which the patients made when registering at the clinic. The same consideration is given to the principal observations made at examination, including roentgenographic signs. Special attention has been paid to mental phenomena. The side of the brain involved by the tumor has been considered in relation to the occurrence of grand mal, aphasia and mental change

ABSTRACT OF DISCUSSION

DR. ALFRED W. ADSON, Rochester, Minn. In reviewing with Dr. Voris this series of tumors of the frontal lobe in which increased intracranial pressure and changes in mental and psychic reactions were not accompanied by motor sensory or reflex disturbances, I have looked for symptoms that might indicate the lobe involved. Unfortunately the description of the psychic changes was not always recorded. I have been sufficiently impressed by the phenomenon that right-handed patients with tumors in the right frontal lobe are euphoric, are agreeable and lack fear whereas right-handed patients with

tumors in the left frontal lobe are morose, surly and obstinate, to consider it worth while recording such symptoms. I have not had occasion to observe whether the converse is true for left-handed patients. All psychic changes are altered when the intracranial pressure increases to the extent that coma results

DR. F. J. GERTY, Chicago. The authors found that there was some evidence of mental symptoms in 70 per cent of the patients with frontal lobe tumors. The study has been primarily a neurologic one. It would be of interest to know whether uniform psychiatric examinations were made in any considerable number of the cases presented here. Eight evidences of mental disturbance were shown. The most frequently encountered symptom was emotional indifference or the indifference of a patient to his condition or his environment. Intracranial pressure phenomena and other somatic disease may present symptoms of this kind. The next mental symptom noted was loss of memory. It would make some difference what sort of memory defect was present. A destructive retrograde amnesia, such as is found in dementia, would need to be distinguished from the failure of memory, because the patient was in an unfavorable condition to recall accurately past conditions. Personality and character change was the next symptom in order of frequency. These patients are under a toxic, organic type of stress. Two possibilities are to be considered with regard to symptoms of this type. First, organic stresses may bring out or exaggerate personality tendencies that are already present in the individual. Second, and it seems to me more important, clouding of consciousness renders the patient more a creature of his automatic reactions and he is dependent on suggestions either from within or from without. The drowsy states and disorientation were next listed. They probably have a similar explanation, the degree of clouding of consciousness and the indifference to environment being greater in both disorientation and in drowsy states. My own experience would indicate that spatial and temporal disorientation usually go together as the authors have found. Disorientation probably does occur more commonly than it is discovered. However, the patient's condition with regard to orientation varies from time to time with the intensity of his symptoms, and it also varies with the conditions under which he is examined. For instance, darkness and confusion changes in environment tend to cause disorientation. Delirious states are listed separately. Euphoria was noted in thirty-four instances and depressed states in twenty-four. Taking all of the mental symptoms described as a group I am of the belief that they indicate the fairly natural mental responses to discomfort, impaired sensation and clouding of consciousness. The latter may be partially protective. The relation of orientation to special areas of the brain is very doubtful. Disorientation must still be regarded as a general effect. Certain psychogenic effects must be allowed for

DR. LLOYD H. ZIEGLER, Albany, N. Y. The apparent discrepancy between the authors' observations and those of others regarding the length of the clinical course produced by the malignant glioblastoma group is not easy to explain. It may be related to certain disabilities of observation that arise when the frontal lobes are the victims of a destructive lesion. Isolated symptoms, such as nystagmus or pyramidal tract signs, are not easy to interpret. Drs. Woltman and Kernohan have demonstrated that a neoplasm may push the brain in such a way as to produce pyramidal tract signs on the side of the lesion. Symptoms and signs may be produced by edema adjacent to the lesion also by occlusion of blood vessels affecting brain areas at some distance from the site of the neoplasm. While patients with frontal tumors present outstanding difficulties to psychiatric study, further detailed observations over longer periods of time would doubtless clarify much that is obscure. Sometimes the symptomatology changes profoundly after from 100 to 200 cc. of 50 per cent dextrose has been administered intravenously. How many of the symptoms are on the basis of delirium due to brain swelling and the absorption of destroyed brain products, and how many on the basis of fundamental failure in brain support, is not clear

DR. ADRIAN VERBRUGGHE, Chicago. From the tables it is obvious that there are many similar signs in both cerebellar and frontal lobe tumors and it seems to me that this difficulty in decision offers one of the chief indications for ventriculog-

raphy as often this is the only means of accurate diagnosis in these cases. Occasionally in frontal lobe tumors the syndrome of Foster Kennedy develops and here one may find an elevation of one optic disk and a primary optic atrophy of the other. In these cases the tumor will be found in the frontal lobe on the side of the primary optic atrophy. If for some reason a ventriculogram cannot be made, it may be wise to place the patient in a free down position for a few moments and tap the ventricles. If bilateral internal hydrocephalus is found, of course the tumor is cerebellar, at least in a vast majority of cases, but in an exceptional few it may be found on the third ventricle. However, if one dilated ventricle is found and the other ventricle is collapsed, the tumor will be found on the side of the collapsed ventricle. The length of the history is not always a guide to the type of tumor to be found, as it is known that patients present themselves with a short history which has lasted not more than three weeks or a month, and at operation a meningioma is found and a tumor that has obviously been growing for years. The shortness of the history in these cases may perhaps be explained by the sudden failure of the venous circulation around the tumor, with a resulting fairly well localized cerebral edema.

DR H. C. VORIS, Rochester, Minn. I thank every one for their part in the discussion, and particularly Dr Gerty for discussing so thoroughly the mental disorders, which we hardly had time to cover adequately in the presentation. In respect to Dr Verbrugghen's remarks about the syndrome of Foster Kennedy, we haven't made as yet a separate analysis of the thirty-three basofrontal tumors in the group, feeling that they warranted separate consideration at a later date. However, they were included in the entire series because we hoped to present, as far as possible, an adequate picture of the observations for the entire group of frontal lobe tumors.

THE TREATMENT OF PERMANENT PARALYSIS OF THE DELTOID MUSCLE

S. L. HAAS, M.D.
SAN FRANCISCO

Permanent paralysis of the deltoid muscle causes a crippling, disabling deformity of the arm with the resultant loss of power of abduction of the involved extremity. When conservative treatment, extending over a period of one year, has failed there remain several methods of surgical treatment by which, if successful, varying degrees of function may be restored to the paralyzed member. The results of neurotization and nerve transference with anastomosis are of doubtful value.

There are two methods, namely, arthrodesis and muscle transposition, that have established their practicability, as evidenced by a number of successful results. Each of these methods has its advantages and disadvantages. In favor of arthrodesis is the greater likelihood of success and the greater strength and power of the functional force at the shoulder, at the expense of mobility. In favor of muscle transposition is the possibility of greater range of motion at the shoulder but with less power than in an arthrodesis. After a successful muscle operation there may be almost normal range of motion, while in an arthrodesis it is usually limited to 90 degrees and many useful movements cannot be performed, such as putting the hand in the pocket, back of the head, or to the opposite side of the body.

With an arthrodesis there is a greater likelihood of fracture in falling or when an abnormal strain is put on the already atrophied bone. Scoliosis may be produced or exaggerated by an arthrodesis. In bilateral paralysis a bilateral arthrodesis would be rather cumbersome and leave the patient still more amenable to injury. In cases in which it may be necessary to ankylose the elbow joint on the same side, it would be preferable to have a movable shoulder joint with greater range of motion.

When there is associated paralysis of the other extremities that preclude the possibility of hard work, a movable joint is better than a stiff joint. Also in the female, for cosmetic reasons, a muscle transposition is advisable rather than an arthrodesis, as in the latter the arm often projects out from the side and there is a flaring out of the scapula.

Under 8 years of age an arthrodesis is not successful, while a transplanted muscle operation may give a good result. If muscle transplantation fails, arthrodesis may be resorted to subsequently if desired.

The available muscles at the shoulder joint to take the place of the paralyzed deltoid muscles are the trapezius, triceps, biceps, coracobrachialis, pectoralis major, teres major, latissimus anguli scapulae and latissimus dorsi.

It is rather strange that so little is mentioned in textbooks on orthopedic surgery about muscle transposition for deltoid paralysis, in view of the fact that there are numerous articles reporting successful results. Of the earlier reports Hoffa¹ in 1902 released the insertion of the trapezius muscle and transposed it into the deltoid with a satisfactory result. A number of others, including Gersuny, Kiliani and Lewis, have also utilized the trapezius. It is interesting to note that Kiliani² in 1910 recognized that the coexisting dislocation should be corrected at the same time. His method of operation consisted of severing the capsule on the humerus three fourths of the distance about the circumference and sewing it to the periosteum of the humerus $2\frac{1}{2}$ inches down the shaft. He then sutured the long head of the biceps in a double loop to hold the head up to the glenoid, using a principle similar to the one employed by Nicola in the treatment of habitual dislocation of the shoulder. Kiliani finally mobilized the insertion of the trapezius and sutured it to the raised up piece of the deltoid muscle. Lewis³ in 1910 reported the results of a similar operation on a patient with paralysis of the deltoid.

Hildebrandt, Sachs, Samter, Shepelman and others, with their individual modifications, have transferred the origin of the pectoralis major to the acromion and clavicle and obtained about 90 degrees of motion. Hildebrandt's⁴ work in 1906 laid the foundation for this method when he transferred the entire origin of the pectoralis to the clavicle and acromion process and obtained about 90 degrees of abduction.

Sloman, Schmidt, Stoeffel and Ober have used the triceps either alone or in conjunction with another muscle to take up the function of the paralyzed deltoid. Sloman⁵ in 1915 transferred the origin of the long

head of the triceps to the acromion process. Recently Ober⁶ has reported successful results from transference of the origin of the long head of the triceps and short head of the biceps to the acromion process.

Riedel⁷ has transposed the entire teres major, leaving its nerve and blood supply intact. The origin of the muscle is anchored to the spine of the scapula, while the insertion is sutured to the humerus near the insertion of the deltoid muscle. The pectoralis minor and

levator anguli scapulae have been utilized in conjunction with other muscle with increased function of the arm.

Lange,⁸ Bradford,⁹ Essers and others attached the trapezius to the humerus with so-called silk tendons and report satisfactory restoration of function.

Fascia lata has been used to prolong the trapezius so that it can be attached more securely to the humerus. Payr¹⁰ in 1913 attached a strip of fascia to the trapezius and then sutured the free end of the fascia to the long head of the biceps. Gallie and Le Mesurier¹¹ in 1921

Fig. 1 (N. A.)—Range of motion of left arm before operation.

interwove strips of fascia lata into the trapezius muscle and then attached the free ends to the humerus, obtaining satisfactory results. Hesse¹² resected the trapezius with the periosteum from the clavicle and, after abducting the arm, inserted the periosteum into the deltoid tubercle of the humerus. This, in conjunction with the pectoralis major transplant, gave an excellent result. Stoffel¹³ freed the insertion of the trapezius from the clavicle and the spine of the scapula and sutured a piece of fascia lata about the raised up end. He then anchored the free end of the fascia lata to the humerus at the deltoid eminence. Mayer¹⁴ in 1927 presented a somewhat similar operation whereby he sutured a piece of fascia lata to the raised up trapezius muscle and, after passing the fascia strip through a ditch prepared in the spine of the scapula, inserted the free

end of the fascia into the humerus near the insertion of the deltoid.

In deciding on which one of these operations is the most suitable for a complete paralysis of the deltoid, a number of factors must be taken into consideration. In the first place the muscle to be transferred must be strong enough to carry on the function of the muscle for which it is to be substituted. Naturally the decision as to which one is preferable, either alone or in combination, depends on the strength of the available muscles, the operative adaptability, and the most advantageous pull on the arm. The trapezius is more likely to be spared in paralysis of the arm and to possess the necessary strength than the other muscles. It also occupies a more advantageous position for a direct pull in the frontal plane of abduction. The pectoral muscle may be efficient but its transference is not so easy and its pull not so efficient, unless the whole muscle is shifted, which, in the female, may be disfiguring. The triceps alone is not sufficient unless the short head of the biceps or the pectoral is used to assist it.

It is believed, taking all factors into consideration, that the trapezius muscle is the most acceptable muscle for substitution for the paralyzed deltoid muscle. In the series of operations to be reported, the Stoeffel-Mayer type of operation has been used with various modifications to prevent or correct dislocation of the shoulder joint.

METHOD OF OPERATION

An incision beginning well out on the spine of the scapula follows along the spine to the acromion process and then to the outer third of the clavicle. The insertion of the trapezius is freed from the spine of the scapula and clavicle, care being taken not to include the supraspinatus muscle. The trapezius is then mobilized so that it forms a tongue-like mass, care being exercised to protect its main nerve and blood supply. A sufficiently long and wide strip of fascia lata, removed from the thigh, is now sutured to the raised up trapezius muscle with heavy braided silk. A ditch is cut out

Fig. 2 (N. A.)—Result five years after trapezius fascia transposition. Five months after original operation it was necessary to free the adhered new formed tendon and surround it with a fat graft.

of the spine of the scapula just back of the acromion process and the free end of the fascia lata is passed through this ditch and over the apex of the shoulder in the subcutaneous fat to an incision that is made over the lower part of the paralyzed deltoid muscle. Through this second incision a rectangular piece of bone is removed from the humerus near the deltoid

eminence and the free end of the fascia is brought down to this opening in the cortex, through which it is passed and then sutured to the surrounding periosteum.

The results following this type of operation were at first quite good, but after a lapse of time there was a decrease in the range of motion. It was found that as the fascia passed through the ditch prepared in the acromion process it often became adherent to the bone,

Fig 3 (C. R. aged 5 years) —Range of motion of right arm before operation. This patient obtained a full range of abduction after a trapezius fascia transposition. She then relapsed to the original condition.

thus accounting for loss of function. It was necessary when this occurred to reoperate to free the fascia strip and surround it with free fat graft. These reoperations¹⁵ presented an opportunity to study the union of fascia with muscle and, as reported in a previous paper, a direct union takes place and the fascia lata takes on a tendon-like appearance. In the more recent operations the ditch in the spine of the scapula has been dispensed with and the fascia is brought over the acromion process as a flat band, anchored in several places to the deltoid muscle, or passed under the perimysium. The distal end is then passed under a raised up spicule of bone near the deltoid eminence and sutured to the surrounding periosteum. The low insertion is of considerable advantage because of the added leverage obtained on the humerus.

It was also noticed that the muscle fascia operation, which worked at first quite well, later lost a great deal of its power, owing to a shift of fascia transplant. When these failures were studied it was found that a

causative factor for the shift in line of pull was usually a luxation of the humerus from the glenoid fossa. A careful check of the more recent cases shows that there is often an associated luxation of the shoulder in paralysis of the deltoid. This is to be expected when one figures that the strong deltoid muscle capping the shoulder joint helps to keep the humerus in its normal apposition to the glenoid.

If there has been a failure of adequate protection by a brace there is further stretching of the capsule, which predisposes for a dislocation. It may not be amiss to call attention to the fact that an abduction brace, when applied so as to hold the arm in the frontal plane of the body, has the pernicious effect of forcing the head of the humerus out of the glenoid cavity. It is therefore important in the conservative treatment by braces or plaster, or for protection after the operation, to see that the arm is directed a little anteriorly to the frontal plane of the body.

This frequent coexisting luxation whenever present demands treatment either before or at the time of the muscle operation. The Kiliani-Nicola, Henderson or Kirchner-Fowler types of operation are adaptable for the paralytic type of dislocation. The Kiliani-Nicola operation has been found to be preferable, as it is relatively easy to perform and can be done at the same time as the muscle fascia operation.

Before the fascia transplant is anchored to the humerus, the long head of the biceps is exposed by dissecting through the atrophied deltoid muscle. By modifying the original operation of Kiliani-Nicola, the biceps tendon is cut in two and the proximal piece is passed through the humerus medial to the greater tuberosity in dislocations to the medial side, while in the lateral or posterior displacements it is passed lateral to the tuberosity. In so doing the operator obtains a corrective pull on the head of the humerus toward the glenoid cavity.

Since it has been recognized that the dislocation of the shoulder joint is a hindering factor, either primarily or secondarily, its correction naturally improves function. As mentioned previously, the luxation changes the line of pull and prevents a strong fixation of the head in the glenoid. The importance of this fixation of the head of the humerus has been emphasized by Mayer, who showed that the first 90 degrees of motion after a trapezius-fascia transference

Fig 4 (C. R. April 28, 1934) —Full range of abduction after second operation consisting of a transposition of the long head of the biceps to the acromion and Kiliani-Nicola operation for dislocation of the shoulder.

¹⁵ Haas, S. L. Free Fascial Grafts. Their Union with Muscle. California & West Med. 32: 387 (June) 1930. The Union of Grafts of Live and Preserved Fascia with Muscle. Arch. Surg. 23: 571 (Oct) 1931.

is a fixed rotation of the humerus and scapula. Any subsequent abduction is a free motion between the scapula and the humerus, due to the pull of the biceps, coracobrachialis or pectoralis major. This is the reverse of the normal movement of the upper extremity in abduction. In some of the patients following the oper-

TABLE 1—*Functional Results Obtained from Operation Trapezius Fascia Transposition*

	Good 12	Fairly Good 6	Fair 7	Failure 5
Good	110 to 180 degrees of abduction			
Fairly good	90 to 110 degrees of abduction			
Fair	45 to 70 degrees of abduction			
Failure	Less than 45 degrees of abduction			

ation, the mechanism of motion is found to be similar to the normal movements of abduction.

ANALYSIS OF THE RESULTS

There were thirty-two patients with deltoid paralysis who were treated with muscle transposition operations. The trapezius with a fascial prolongation was employed in thirty, the pectoralis major in one and the teres major in one. The triceps and biceps were used in two cases to supplement the trapezius muscle. In two cases there was a bilateral abductor arm paralysis. In one of these cases a muscle transposition was performed on one side and an arthrodesis on the opposite side, while in the other a muscle transposition was performed on both sides.

In the operation using the pectoralis major a fair functional result was obtained. This result could be improved on by transposing the muscle toward the acromion process.

TABLE 2—*Strength of Accessory Muscles at the Time of Operation*

Good 9	Fairly Good 10	Fair 5	Poor 6
-----------	-------------------	-----------	-----------

In the biceps-triceps transposition the result was very good.

There were three patients in whom a primary arthrodesis at the shoulder joint was performed with the usual function for an arthrodesis.

The results of the thirty operations in which a trapezius-fascia transposition was performed are given in the tables.

In more than half the cases of this series, a satisfactory functional result was obtained.

In comparing the number of good results as shown in table 1 with those showing good strength of the accessory muscles as shown in table 2, it will be noticed that there is a direct relationship between the strength of the transposed and accessory muscles and the functional result obtained by operation. The stronger the transposed muscle and accessory muscle, the better the result.

The Kiliani-Nicola type of operation was used in twelve of the seventeen cases. In these seventeen cases the muscle study showed that the strength of the accessory muscles was weak in thirteen. In other words, there is a greater tendency to dislocation when the associated muscles are weak.

In more than half of the cases either a good result or a fairly good result was obtained, even though the muscles were weak in a majority of the cases. This increased function obtained even with the weak muscles must be attributed to the added fixation obtained by the operation. The mechanism of the trapezius muscle fascia transposition is, in the major part, a movable arthrodesis, hence the necessity of a good fixation at the shoulder joint.

There were eight patients with a combination of shoulder and elbow paralysis. In three the results were good and in five fair (table 5). Considering the extensive paralysis, these results offer a fair degree of encouragement for a successful result in an apparently hopeless extremity.

The trapezius muscle was strong in almost two thirds of the cases. This is twice the total of the other three muscles and establishes it as the muscle most preferable for transference in deltoid paralysis.

SUMMARY

The stronger the trapezius and the accessory muscles, the greater is the possibility of a successful outcome for the operation.

TABLE 3—*Type of Operation for Associated Dislocation*

Kiliani Nicola 12	Henderson 8	Kirschner Fowler 1	Combined Fascia and Bone Graft 1
-------------------------	----------------	--------------------------	--

It was found that a long period of protection by an abduction brace, and muscle training extending over a period of from six to twelve months, was important. In the earlier treatment, when the brace was dispensed with too soon, an apparently successful result was followed by a gradual loss of function.

In cases of partial failure from a trapezius transplant, some other muscle, such as a triceps, teres major or part of the pectoralis major, may be transposed to give the necessary added power.

It is important to treat the frequently associated dislocation of the head of the humerus previous to or at the time of the original operation. In children, the Kiliani-Nicola type of operation is satisfactory.

In a number of cases of this series only a partial result at best could be expected, as there was not sufficient muscle power to warrant either a muscle operation

or an arthrodesis. It was thought worth while, however, to attempt to restore some function to these absolutely helpless extremities and, although perfect results have not been secured in these cases, sufficient function has been obtained to justify the operation.

It is to be noticed that in a number of the cases there was also complete loss of function at the elbow joint and partial disturbance in the wrist and finger motion. In spite of these additional handicaps, which also demanded operative treatment, a number of the extremities have been restored to a fair degree of usefulness.

The average age of the patients at the time of operation was 9 years. The youngest patient operated on was 6 years of age and the oldest 14 years of age. The average duration of the disease before the operation was four years. All but a few of the patients recently operated on have been under observation from one to six years.

TABLE 5—*Combination of Paralysis at the Shoulder and Elbow Joints. Functional Result from Operation*

Good	Fairly Good	Fair	Failure
3	0	6	0

In girls and those patients with severe paralysis of other extremities, and for most patients in general who will lead a more or less sedentary life, a muscle transplantation is preferable to an arthrodesis because of the better cosmetic results, the greater range of motion, and the less likelihood of subsequent injury to the patient. In case of failure from a muscle operation one can still resort to an arthrodesis.

CONCLUSION

Transplantation of the trapezius muscle, with a fascia lata prolongation into the humerus is a rational procedure for treatment of paralysis of the deltoid muscle.

It is important to treat the coexisting dislocation at the shoulder joint at the time of the original operation or subsequently, should it develop.

The stronger the accessory muscles, as the pectoralis major, biceps, coracobrachialis and scapula muscle, the better the result. However, in a number of patients without the prerequisite strength of the muscle and in

addition an associated paralysis of the elbow joint some gratifying results were obtained in apparently hopeless extremities.

A long period of postoperative physical therapy and protection from strain, up to a year if necessary, is important in obtaining the maximum effect of the operation.

450 Sutter Street

ABSTRACT OF DISCUSSION

DR. JAMES A. DICKSON, Cleveland. Dr. Haas made a thorough analysis of his cases before and after operation and he has a series sufficiently large to make his conclusions a valuable contribution. Many have been prone to accept the arthrodesis of the shoulder as being sufficient in some of these cases. Dr. Haas has demonstrated the advantage of the possibilities of tendon and muscle transference. I believe the importance he has laid on the stabilization of or the luxation of the shoulder joint by the Nicola procedure cannot be too strongly emphasized because the underlying principle is of the greatest importance in this work. In my own work I have not used the trapezius except in cases in which there is a good biceps and triceps. I have found that the Ober operation with fixation to the acromion has given me the most satisfactory results. Dr. Haas has demonstrated the advantage of making use of the trapezius and has stimulated me to use this method more often.

DR. A. H. BRISTWATER, Boston. I should like to compliment Dr. Haas on the results he has shown and relate our experience in the Children's Hospital in Boston. Quite a number of times we have attempted trapezius transplants, putting fascia underneath the trapezius, running the fascia band through another tube of fascia, but the results have not been anything like Dr. Haas's. I think, as he said, the accessory muscles must be good and that is one of the most important conditions. On examining a number of the trapezius transplants that regain power, one will find often that a weakened deltoid has been helped by the transplant and is doing part of the work. Going on to the transplantation of the triceps and biceps, we have found the biceps, the short heads of the biceps, if good or normal is almost in itself sufficient to raise the shoulder and put it through normal function. We have combined the Nicola operation with that of Dr. Ober and we have found, as Dr. Haas has, that it is necessary to take care of the subluxation of the shoulder joint. I believe that a combination of these operations, when the biceps and the triceps are weak, is often very satisfactory.

DR. ROBERT D. SCHROCK, Omaha. When Dr. Haas's paper is published those who read it critically will have as much pleasure in it as we have had in seeing the beautiful demonstration of its effectiveness. The chief point to me was the careful discernment detailed analysis of the individual case from the standpoint of muscle power before the determination of the procedure to be done and also the vocational adaptability of this individual during the years to come.

DR. WALTER A. HOYT, Akron, Ohio. It is unfortunate that every one couldn't have read this paper first because it is a real contribution. I am sure that all are going to enjoy reading it. Orthopedic surgeons have been going through with the shoulder very much what they did with the foot for so many years—transplantation done promiscuously, without any real reason or careful determination of the muscle power and of course, with many bad results. It was not until some method of stabilization of the foot was developed that transplantation became successful. To me, the most important part of Dr. Haas's paper is the stabilization, the so-called movable stabilization of the head of the humerus. If that is true (and I think the pictures show that the head remains stable during the motions) it seems to me that, rather than wait until one sees whether there is a luxation after the transplantation is done, it should be performed as a routine procedure with the transplantation because in many of the cases Dr. Haas reported a secondary operation was required. I should like to ask Dr. Haas what position he puts the shoulders in. I had an experience a year ago in doing an operation in a case of Sprengel's disease, of having a paralysis of the whole arm develop much the same as in the case reported by Whitman and in one other by Dr. Roy Abbott. In those cases there was no trauma that could account for the amount of paralysis. I wonder whether in some of these cases one might find the same thing taking place in the fixation. It would be rather difficult to recognize because of the already marked amount of paralysis. Maybe that accounts for some of the bad results.

DR. SYLVAN L. HAAS, San Francisco. All of these patients had been treated conservatively for at least a period of a year, and most of them for two years, without showing any sign of return in the paralyzed deltoid so I don't think the operation has had any effect on the deltoid muscle. It has increased the fixation of the humerus to the glenoid. In answer to the questions of the position the arm is generally placed at 110 degrees of abduction either in plaster or in a brace. The most important point to realize is that one must not take away this protection too soon. I started physical therapy at the end of seventeen days. At first I used to keep the arm up for three months but found, as may have been noticed in one boy shown, that they often relapse and lose what was gained. By continuing with the protection for almost a year and watching carefully, one gets much better final results. The transposed muscle must regain strength just like a muscle that is paralyzed after poliomyelitis. The longer the time of fixation, the better the result. It not only increases the strength of the muscle but it gives better fixation in the glenoid.

THE SURGICAL TREATMENT OF ULCERATIVE COLITIS

RICHARD B. CATTELL, M.D.
BOSTON

The treatment of ulcerative colitis is primarily a medical problem and fortunately most patients with this disease respond reasonably well to a carefully regulated medical management. In some patients these conservative measures are insufficient to control or arrest the disease, and surgical treatment is indicated and necessary for relief. As the result of recent interest and study of ulcerative colitis there have been many reports dealing with the etiology, diagnosis and medical management of these cases, so that at present the disease is suspected earlier in its course and its presence is proved by proctoscopic examination and the barium enema. There have been fewer reports dealing with the surgical treatment of the intractable cases. It is my purpose in this discussion to present a group of these patients treated at the Lahey Clinic by ileostomy and by partial and complete colectomy and to outline indications for operation and the results of this operative treatment.

The surgical treatment of ulcerative colitis aims first to put the infected colon at rest by diverting the intestinal contents on the abdominal wall. This in theory permits the greatest degree of healing possible, since the ulcerative surfaces are not constantly traumatized and irritated by feces. Secondly, it permits removal of the infected bowel and eradication of the complications associated with the disease. A third purpose should be mentioned—that of irrigation of the involved bowel by establishment of a fistula above the infectious process. In my opinion this is not of great value, since all that can be accomplished by this means can be obtained by irrigations through the rectum.

It is impossible in this paper on the surgical treatment to discuss the clinical course and the diagnosis of ulcerative colitis, but there are certain aspects that must be considered for a proper application of surgical therapy. The disease varies within wide limits in its severity. While it may be mild with few symptoms, it frequently runs a chronic course with acute exacerbations and recurrences. The ulcerative process usually begins low in the large intestine in the rectum or rectosigmoid but tends to extend to the colon so that all of the large intestine becomes involved. In relatively few patients does the process remain localized for a considerable period. The infection is not limited to the mucous membrane but tends to involve all of the wall, so that in addition to the large areas of mucosal ulceration the muscular wall becomes markedly thickened and the serosa is found to be edematous and injected. In this severe and chronic form the secondary complications of the disease are frequent.

There are a number of complications that may occur in ulcerative colitis. Acute and subacute perforations may occur in the acute fulminating form of the disease. These occur in the deep, punched out ulcers and usually result in a fatal peritonitis. Operative treatment in these cases is of no benefit in the form of either simple peritoneal drainage or closure of the perforation. These

patients too are in such poor condition that neither a localized nor a spreading peritonitis can be withstood. Perforation in the chronic cases, on the other hand, usually leads to localized abscess formation within the peritoneal cavity or abdominal wall or results in fistulas between adjacent loops of intestine, or fistulas between the colon and the bladder, vagina or perineum. Surgical treatment in this group offers a definite chance of relief, since resection can be carried out following permanent ileostomy. Polypoid degeneration of the remaining mucosa is another complication encountered. It occurred in five of our patients at the clinic and was reported in 10 per cent of the series studied by Bargen and Comfort. These polypi may encroach on the remaining lumen of the bowel so that drainage of the mucus, pus and blood from the infected area is ineffective. Malignant degeneration of these polypi has been reported but was not encountered in our patients. The development of partial or complete obstruction in the colon is a not infrequent finding and offers a definite surgical indication. The recurrent ulceration and inflammation of the colon and rectal wall is followed by partial healing with accompanying fibrosis, so that a marked narrowing of the lumen occurs and has in two of our patients produced complete obliteration of the lumen at one or more points. In four patients the stricture formation in the rectum was so extensive that a digital examination beyond the anal sphincter was impossible. The last serious complication of surgical significance is the recurrence of symptoms associated with general malaise, fever and local bowel symptoms. In these patients, who are apt to be entirely incapacitated during recurrences, surgical treatment seems indicated.

From a consideration of these complications, we feel that surgical treatment is at times indicated in the long standing recurrent cases of ulcerative colitis. We do not believe that the indication for surgery in the acute cases can be so clearly defined. Every one dealing with this problem has seen patients in the first attack of ulcerative colitis go progressively downhill with a fatal termination in spite of medical measures. On the other hand, some of these acute cases respond reasonably well without surgical intervention. This leaves one rather in a quandary as to the selection of cases of this type for ileostomy. I can simply state that it is our practice at present to place these patients on medical management, and if they do not show a satisfactory response after from two to three weeks' treatment, a transverse ileostomy is carried out. It must be recognized that surgical intervention in these acute cases is very serious and a high operative mortality must be accepted.

In the chronic cases, the proctoscopic examination and the barium enema will reveal the extent of the process and will suggest the degree of function that can be expected in the involved bowel. When the haustral markings are absent in the roentgenographic examination and the colon appears rigid and of the "lead pipe" type, when digital and proctoscopic examinations indicate marked destruction of the rectum, we feel that permanent drainage above the involved portion is indicated. This brings up the consideration of ileostomy or colostomy as a permanent drainage in these cases. Early in our experience we performed ileostomy with the idea of utilizing it as a temporary measure in order to permit healing of the infected bowel while at rest. After we had observed patients for considerable periods of time after ileostomy, it was found that the colon showed

little evidence of sufficient healing without stricture formation to permit reestablishment of the intestinal tract. We feel very strongly that in those patients with ulcerative colitis in whom an ileostomy is considered it must be accepted as a permanent drainage, and we have in no case felt justified in reestablishing the intestinal continuity. Certainly in adult patients the catch phrase "once an ileostomy always an ileostomy" can be said to express the situation.

The necessity for colostomy in the treatment of carcinoma of the rectum is now accepted, since it is well recognized that a patient with colostomy can manage it without serious difficulties. It has been repeatedly stated in the literature that a permanent ileostomy creates a deplorable situation because of difficulty in the control of the liquid discharge of feces. We have learned that ileostomy can be handled with only moderately more difficulty than can a colostomy. Certainly ileostomy can be tolerated by most patients for indefinite periods of time without impairment of health if the disease itself can be arrested. A dietary deficiency state, similar to pellagra, has been reported but is rare. In the acute cases it is very important to realize that a large amount of fluid is lost following ileostomy, together with substances of food value but especially the chlorides may be depleted. The level of the blood chlorides must be followed carefully following operation, and it is necessary to give large amounts of dextrose and saline solution to compensate for this loss. It is quite probable that some of the postoperative deaths result from depletion of the chlorides and starvation. It has been our observation that the function of fluid absorption in the colon can be partially compensated for by fluid absorption in the terminal ileum. We have been impressed by the fact that patients with ileostomy who have subsequently had complete colectomy tend to have semisolid movements from the ileostomy, whereas patients with ileostomy with the colon still present shows less tendency to fluid absorption by the ileum. Three of our patients with ileostomy who have had complete colectomy manage their ileostomies and are able to carry on a normal activity (fig 1). Each wears a colostomy belt both day and night, and they find it necessary to empty it three or four times a day but not during the night. In these patients irritation of the abdominal wall at the site of the ileostomy has been intermittently present, but at all times under control and not interfering with wearing of a colostomy apparatus. The fact that ileostomy can be managed in these patients while carrying on an active life justifies its performance in those patients who cannot be relieved by medical measures. It would be misrepresenting the facts to state that ileostomy is not a serious inconvenience, and I do not wish to imply that it is not, but it should be pointed out that this difficulty has been greatly exaggerated in previous reports.

The technic of ileostomy is relatively simple. It must completely divert the intestinal content so that the tube ileostomy is not satisfactory. We prefer a right rectus incision and make no attempt to utilize the muscles of the abdominal wall for any possible sphincteric action. Under local or spinal anesthesia the terminal ileum is identified without exploration of the abdomen and with as little handling of the intestine as possible. The point is selected 4 inches from the ileocecal valve and the ileum divided transversely between clamps, care being taken not to interfere with the blood supply of

the mesentery of the distal ileum. The two ends are then drawn out together and the layers of the abdominal wall closed loosely about them. The intestine is not sutured to peritoneum, fascia or skin, but it is held in place by the clamps with dry gauze next to the skin to aid in the formation of adhesions. The rent in the mesentery is anchored to the peritoneum in order to prevent any prolapse of either segment. The clamps hold the bowel in position until firmly anchored by adhesions. In patients with severe toxemia the catheter is immediately sewed into the proximal segment, but in the less severe cases drainage is delayed for twenty-four hours. We have on occasion approximated the proximal and distal loops in the form of a Mikulicz spur, so that later reestablishment of the intestinal tract could be obtained extraperitoneally. Thus we now feel is not indicated, since there is no prospect that the condition of the colon will permit it. In case ileostomy is done definitely as the first stage of colectomy, the distal ileum may be inverted and dropped into the abdomen as suggested by Rankin, but this should not be

done unless it has been shown by the barium enema that no obstruction is present within the colon.

In the past, appendicostomy has been utilized by a number of surgeons in the treatment of ulcerative colitis. This has been employed for the sole purpose of providing a means of irrigation of the bowel without diverting the intestinal content. While it is still being employed in certain clinics, it has for the most part been discarded either for medical management or for

Fig 1—Usual double-barreled transverse ileostomy performed two years previously. This ileostomy was placed just to the left and below the umbilicus to facilitate complete colectomy. The recent incision on the right was made when the first stage of complete colectomy was performed. There is an absence of skin digestion and no tendency to prolapse of either proximal or distal ileum.

more radical surgical procedures. Cecostomy, on the other hand, offers more definite advantages, particularly in those cases in which the disease is limited to the lower bowel. When employed, it would seem best to deliver the entire cecum outside the abdominal wall rather than to employ a tube cecostomy. We have not used either of these operations with one exception, so they will not be discussed further. Colostomy, on the other hand, done well above the involved portion of the bowel in patients in whom the disease is limited to the sigmoid or rectum, has been of value in our hands. In two cases in which the disease was limited to the sigmoid and rectum we made a loop colostomy in the left colon. Further observations showed that the disease extended above the colostomy, so that the entire large intestine later became involved. However, in two other cases colostomy was done in normal bowel and was followed by the abdominoperineal resection of all the bowel below the colostomy. In neither of these cases has the disease recurred in the remaining colon. I feel that valuable

information is offered from a consideration of these four cases. The progress of the disease proximally was not arrested in either case of colostomy in which the involved bowel was left in place, whereas both patients who had complete removal of the involved bowel after colostomy have remained well. In the first two cases the disease progressed within a few months above the colostomy, so that it seemed important to carry out the resection within a few weeks of the preliminary drainage.

Partial colectomy or segmental resection of the colon is of value in few cases. These must be selected with great care, based on careful sigmoidoscopic examination and a barium enema, confirmed by careful examination of the entire colon at the time of operation. It must be appreciated that it is very difficult to be certain of the limitation of involvement either by direct visuali-

Fig. 2—Specimen consisting of cecum, ascending colon and half of the transverse colon. The ulcerative colitis was known to have been present for twenty-one years; appendicostomy having been performed by Dr. Lahey in 1912. Contraction, ulceration, polyposis and deformity of the colon are evident.

zation of the colon or by palpation. The more conservative procedure of partial colectomy seems justified at times, but it must be realized that the disease may progress to involve the remaining colon. The technic of partial colectomy is identical to that for carcinoma except that little of the mesentery need be included in the resection. I feel that the modified Mikulicz type of resection should be employed in all colon resections for this disease, and that if the rectum is to be excised it should be done by a two stage abdominoperineal resection in order to avoid the complication of peritonitis.

Because of the usual pathologic changes in the chronic cases of ulcerative colitis when the entire large intestine is involved, complete colectomy will more often be necessary and applicable than partial colectomy. Complete

colectomy is unquestionably a formidable procedure and should be done only in those cases in which relief cannot be obtained by any other means. The technic of complete colectomy will be presented in another communication. It should be done only after a long trial of transverse ileostomy. It should be carried out in two or three stages in addition to the ileostomy. The terminal ileum, cecum and ascending colon and a portion of the transverse colon proximal to the middle colic artery can be resected at the first stage in the more serious cases, followed by the removal of the transverse colon, the descending colon at a second stage, and the abdominoperineal resection of the remaining segment at a third stage. In better risk patients, all of the colon from the cecum to the sigmoid (fig. 5) can be resected, followed by a second stage abdominoperineal resection. Because of the tendency to stricture and abscess formation in the bowel, my associates and I implant the distal loop of the colon in the abdominal wall to provide drainage and to avoid peritonitis. This does not add greatly to the difficulty of carrying out the next stage. While it would be easier technically to attempt to close the distal segment and leave it within the abdomen, this would seem to be unwarranted because of the dangers involved. I feel that the operations should be separated by an interval of at least two months in order to permit the improvement that follows the resection of a portion of the infected bowel.

At the Lahey Clinic, sixty-three patients with ulcerative colitis have been treated. In this group there was a relatively high proportion of serious and complicated cases. Surgical treatment has been carried out in twenty-one cases (one third of the total group) while the remainder have been carried on medical treatment alone. This represents more radical therapy than in other reported series. Ileostomy has been performed fourteen times, and in all these cases the disease involved the entire large intestine. In eight cases the ileostomy was performed for the severe toxemia that was present. In six it was performed as a preliminary to complete colectomy. There were five postoperative deaths following ileostomy, all of which occurred in the acute cases in which there was a severe toxemia. One was the result of a coronary thrombosis. One resulted from an acute perforation of the colon, and the remaining three patients died as a result of the severity of the disease plus some degree of operative shock.

In the six patients in whom ileostomy was done as a preliminary to complete colectomy, one patient died five months later. This patient had had the disease for twenty-three years, and complete colectomy was considered to be the only possible treatment to relieve her condition. At the onset of the disease an appendicostomy had been done, which had been open intermittently for several years. After a two months trial of medical treatment, a colostomy of the transverse colon was done, since the disease appeared to be limited to the lower part of the bowel according to the roentgen and operative observations. It is quite likely, however, that it had already extended above this point, since the right colon was shown to be involved shortly after, and ileostomy was performed to be followed by complete colectomy. A first stage right colectomy was carried out two months later, and she improved somewhat for a few weeks (fig. 2). She then began to fail rather rapidly with the progress of the disease and died.

three months after the first stage colectomy from multiple chronic perforations and fistulas with peritonitis. A second patient has had a remission of the disease for three years following ileostomy and has been free from attacks of chills, fever or malaise. Complete colectomy has since been considered for this patient, but as he continues in remission it has been indefinitely delayed. One patient has had the ileostomy done too recently to permit a decision in regard to complete colectomy. Two patients have had a complete colectomy in two

Fig 3—Abdominoperineal resection of the sigmoid and rectum for ulcerative colitis of two years duration. The disease in this case was strictly limited to the lower sigmoid, rectosigmoid and rectum. This illustration, taken one month after the first stage operation, shows the permanent proximal colostomy in the left upper quadrant with the implanted distal end above the pubis. There has been no return of symptoms in the twenty-two months since abdominoperineal resection.

stages, and one has had one in three stages. All have been well for approximately one year. Each has been able to resume a normal activity, in one acute intestinal obstruction developed four months after colectomy, which was relieved by the division of an obstructing band.

In six cases the involved portion of the bowel was limited, and partial or segmental resection was carried out. In two cases the rectum alone was involved for a dis-

tance of 6 inches (15 cm) with marked ulceration and thickening associated with perineal fistula, rectovaginal fistula and multiple fissures of the perianal skin. Abdominoperineal resection was carried out in two stages in each of these cases, several inches of normal bowel being removed above the involved portion (fig 3). A third patient had involvement of the descending colon, sigmoid and rectum, with obstruction of the sigmoid presenting a defect in the barium enema suggestive of a malignant lesion. A Mikulicz resection was then carried out, the spur between the two loops being left intact in the hope that the process below might subside. In this case the remainder of the colon had become involved, and we felt that ileostomy and complete colectomy were now indicated. These four cases were mentioned earlier in the paper in connection with colostomy. Two patients had the process limited to the colon, the first involving the transverse colon, producing partial obstruction, multiple fistulas of the wall and polypoid formation. A Mikulicz resection of the entire transverse colon was carried out, the cecum being joined to the descending colon. The second patient had involvement of the right colon and had complete right colectomy after the same technic. Both of these patients had subsequent closure of the temporary colostomy, but the abdominal wound broke down, at least temporarily, and subsequently closed spontaneously. The following case report illustrates the value of a segmental resection in ulcerative colitis.

CASE 1—M O, an unmarried woman, aged 39, seen in August 1932, had noticed two years previously that her mouth was sore and shortly afterward a persistent diarrhea had developed. Mucus and blood were passed with severe pain on defecation. Nine months after the onset of diarrhea, arthritis

developed in the knees, shoulders, hands, neck and spine. Tonsillectomy was performed in October 1931 with relief of the sore mouth and some improvement of the arthritis. Previous to our examination she had been confined to bed for five weeks. She had lost a total of 50 pounds (22.7 Kg) from a normal weight of 150 pounds (68 Kg). Recently she had been having small defecations every fifteen minutes and had frequent spells of nausea and vomiting.

On examination the patient was pale and emaciated and appeared acutely ill. The tonsils were absent and the teeth were in good condition. The anterior cervical glands were palpable. The heart was not enlarged and there was a loud blowing systolic murmur heard to the left of the sternum. The pulse rate was 110 with a regular rhythm, and the blood pressure 100 systolic, 70 diastolic. There was tenderness in the left lower part of the abdomen, where the outline of the sigmoid could be made out. The rectum was indurated, contracted and tender. Mucus and pus were found on proctoscopic examination with the typical changes of ulcerative colitis. The barium enema showed the sigmoid to be narrow and spastic, with failure to fill out at any time, while the remainder of the colon beyond this point filled out satisfactorily. She was admitted to the hospital, Aug 24, 1932, her temperature remained over 102 F and the tenesmus and diarrhea were not diminished. Operation was carried out, August 29, because of the severity of the condition and contraction of the sigmoid and rectum. On exploration the process seemed limited to the sigmoid and rectum, so that the descending colon was divided 3 inches above this point, the proximal end being brought out as the end colostomy and the distal end implanted above the pubis as described by Lahey for resection of carcinoma of the rectum (fig 3). A wound infection developed but gradually improved and the patient was discharged from the hospital one month later. At this time she was afebrile and had normal movements by colostomy every three days. The rectal discharge continued, but the tenesmus was much less troublesome. Six weeks after operation she had gained 20 pounds (9 Kg) and felt better than she had at any time since the onset of the disease. Proctoscopy was not possible because of contraction of the rectal lumen to the caliber of one finger. No pus was evident, although digital examination caused free bleeding. Abdominoperineal resection was carried out, November 12, approximately six weeks after colostomy. She was discharged twenty days later in good condition. She has been well without any recurrence of fever for eighteen months. She does not find it necessary to wear a colostomy bag. Inspection and proctoscopic examination of the colostomy shows normal mucosa.

Fig 4 (case 2)—The cecum, ascending colon and hepatic flexure. The total segment is 5 inches in length less than half of normal. The cecum is perforated forming an abscess in the abdominal wall. All normal markings of the colon were absent with replacement of the mucosa by ulcers and scar tissue.

From experience in these cases I feel that in rare instances the disease may be limited to a portion of the intestine where resection of all the involved portion has been possible. Within a short time it seems that these patients have a reasonable prospect of continuing well without spread of the disease. From a consideration of the cases of ileostomy, it will be noted that only one patient has been free from return following this procedure alone. Complete colectomy offers the surest method of complete relief in these serious intractable cases. If properly carried out, it can be done with a low operative mortality. While

the time interval after colectomy has not been long enough to judge whether these patients will remain permanently well, I feel that this procedure offers definite relief in the intractable and complicated cases. The following case report is typical of those treated by complete colectomy.

CASE 2—Mrs. M. S., aged 25, who came under observation in December 1930, for three months had had a severe diarrhea with from eight to twelve loose movements daily containing mucus, pus and blood. She complained of nausea, occasional emesis, fever and loss of weight. She presented the picture of an acute toxemia with prostration. Sigmoidoscopic examination was negative except for the presence of mucus and blood, with a normal appearance of the mucosa of the lower part of the bowel. A barium enema showed a variation in the haustral markings in the cecum and ascending colon and this portion of the bowel was spastic and irregular, while the remainder of the colon filled and emptied normally. The stools were negative for *Endamoeba histolytica* and *Bacillus tuberculosis*. The Craig test was negative.

Fig. 5—The colon removed in a severe case of ulcerative colitis four years following ileostomy. Marked stricture formation is evident at the hepatic flexure and in the descending colon. At one point even a small probe could not be passed through the lumen. The remainder of the large intestine including the sigmoid, rectosigmoid and rectum were removed by abdominoperineal resection two months later. A blind ends B ileum.

After two weeks of medical treatment her condition was unimproved, and she continued to have a 'septic type' of fever. A transverse ileostomy was done in January 1931, the ileum being brought out on the left side, as it was hoped that a segmental resection of the right colon would relieve the condition (fig. 1). Following ileostomy there was a striking reduction in the fever and the patient made satisfactory improvement and was able to leave the hospital three weeks after ileostomy with a normal temperature.

She was seen at frequent intervals, and during the following year she was fairly well, but at no time was she free from diarrhea, and in addition she had recurrences of chills and fever every two or three months. Eighteen months after ileostomy she first showed involvement of the rectum and sigmoid by proctoscopic examination. During the next six months she was totally incapacitated because of the recurrence of all symptoms and abdominal and pelvic pain. A tender mass developed in the right lower quadrant, a rectovaginal fistula was discovered and there was marked pelvic tenderness on bimanual examination. An infectious arthritis developed in

the left ankle. Colectomy was advised at this time, two years after ileostomy.

In February 1933 the cecum, ascending colon and hepatic flexure were resected (fig. 4). The cecum was markedly thickened, contracted and bound down by adhesions, and a chronic perforation into the abdominal wall with abscess was encountered. This total segment measured but 5 inches (127 cm.) in length. She made a good recovery and in two months had gained 19 pounds (8.6 Kg.). Her appetite was good, there was little discharge from the rectum, and she was able to work about the house.

The second stage colectomy was carried out in May the transverse descending colon and sigmoid being removed. At this time a pelvic abscess was encountered, so that the removal of the rectum was considered inadvisable. During the next two months she gained an additional 11 pounds (5 Kg.) and had few residual symptoms. Because of the rectovaginal fistula and contracted and infected rectal segment, it was felt that the remainder of the bowel should be removed to guard against further recurrence.

An abdominal perineal resection and a blood transfusion were performed in July. This was followed by marked shock and a stormy convalescence for the first few days but she was able to leave the hospital in reasonably good condition sixteen days after operation.

Since the complete colectomy she has been well without recurrence of fever. Her appetite is good and her weight is the same as before the onset of the disease. She is able to carry on a normal activity, doing all her work for a family of five. She wears a colostomy bag constantly, and there has been little evidence of skin irritation. The only disagreeable feature reported by the patient is the noisy escape of gas at times from the ileostomy, over which she has no control.

CONCLUSIONS

Surgical treatment is of value in ulcerative colitis, particularly in the chronic cases complicated by fistulas, intestinal obstruction and recurrences of the acute exacerbations of the disease. In these cases the colon has little possibility of carrying out its function and serves as a constant source of infection.

Transverse ileostomy may result in a remission. When performed, it must be considered permanent. It is of greatest value in the chronic cases but may be necessary in the acute cases.

Complete colectomy may be necessary for relief and can be done with a low operative mortality if performed in divided operations. It has been carried out in three patients, who have remained well for one year.

Partial colectomy can be done in selected cases if the involvement is definitely limited to one segment of the colon. It was performed in six patients in this series.

Ileostomy and colectomy are not suggested to replace the medical treatment of ulcerative colitis but are presented as an aid in the management of the intractable and complicated cases.

605 Commonwealth Avenue

ABSTRACT OF DISCUSSION

DR. F. R. PETERSON, Iowa City. It must be admitted that, except for certain acute complications, the treatment of this disease in the beginning is medical and usually remains such. Eventually, for some, a partial or complete colectomy offers the only chance for a cure. However other surgical measures less radical must first be done to assist medical management and must always precede a colectomy. It is concerning the latter group that I wish to say a few words, the facts as presented here not being meant to be conclusive but worthy of consideration. The statements are based on the results of

thirty cases over a period of fifteen years. During each half of this period six ileostomies were done. During the last four years fifteen appendicostomies or cecostomies, if the appendix had previously been removed, have been performed and this procedure has now essentially replaced ileostomy in the clinic with which I am connected. The reasons are that first of all only two of the twelve patients who had ileostomies are now living, second, those with ileostomies are relatively more dissatisfied with their existence, third of the fifteen patients with a tube in cecum only one has died and this from an unrelated cause. The results include acute as well as chronic and recurrent cases. For example, medical treatment failed in one case and an ileostomy was done nine months ago. Since then the patient has gained 30 pounds (13.6 kg), the anemia has been overcome and she now has one bowel movement daily. The procedure consists of insertion into the cecal lumen of a rubber catheter, size 12 or 14 F. As soon as healing is adequate in from three to four days, the colon is irrigated daily or twice daily, depending on the reaction with a liter of 1 per cent sodium chloride solution. When this can be used without reaction, 1.25 per cent and finally 1.5 per cent solution is used if tolerated. Irrigation of the colon is not new. What effect the hypertonic salt solution has is not known. It is not presumed that this will cure ulcerative colitis although one of this group is now clinically well, and the others are markedly improved. If a complete colectomy is later advised of course an ileostomy must precede it, but until then the low mortality, the comfort of the patient and the satisfactory results have caused us to continue this procedure.

DR. ALFRED A. STRAUSS, Chicago. I agree with Dr. Cattell's statements and method. I also agree with his preoperative and postoperative methods. There are a few points to be emphasized in the relationship of the internist to the surgeon in this disease. Since 1917 I have done thirty-two colectomies, with five deaths. In only four was the rectum removed after complete colectomy. Of these deaths three were from pneumonia, one from embolus and one from a lung abscess four months after operation. In addition to these I have done eight ileostomies. Six of the patients remained well without further intervention. Two are only fairly well and probably colectomy will have to be done. In 1917 and 1918 I did five complete colectomies in a one stage operation with one death. One of these patients, whose normal weight was 152 pounds (69 kg), weighed only 58 pounds (26 kg) at the time of the operation. An ileostomy had to be performed with the patient in bed after six or eight blood transfusions. The patient is perfectly well. Of the thirty-two patients, ten have been well since 1918. Four are only fairly well. Contrast these results with fifty-two additional cases that I have seen from the various medical services at Michael Reese and Mount Sinai hospitals. All of the fifty-two patients, whom I saw in consultation died within a few days or shortly thereafter without surgical help, as a result of the severity of the disease. This shows clearly the helplessness of the medical man in combating this disease by medical means. In eleven cases in which ileostomy was done it proved to be of no value. The patients died in spite of multiple blood transfusions. Six of these were performed in bed, the patients being moribund. They are not fit surgical subjects even for so small a procedure as an ileostomy under local anesthesia. Many of these patients died of acute hemorrhage. I do not mean bloody stools, I mean acute hemorrhage. No matter what is done for these patients, they bleed to death because the ulceration gets into a large artery in the colon. Two patients remained perfectly well after the ileostomy was closed. The question arose as to whether this was a chronic idiopathic ulcerative colitis. The ileostomies were done very early. These are the only two cases I know of in adults that it was possible to close and the patients remained well. In one child, aged 8 years, I performed an ileostomy and closed it two years later. She is well now, three years after the closure of the ileostomy. I believe that it is a lymph-borne infection, which infects the entire colon. This is demonstrated by the lymphatic gland involvement and by the marked infection not only of the mucosa but of the submucosa and muscularis. The best medical treatment is an early ileostomy. The internist, then, may do whatever he wishes in administering serums and vaccines.

CONTUSIONS OF THE HEART

CLAUDE S. BECK, M.D.

CLEVELAND

Most wounds of the heart are of the penetrating variety, i.e., they are produced by stabs or bullets that penetrate the heart.¹ However, there is another type of cardiac trauma not produced by penetration of the body and it is this nonpenetrating type of trauma that I shall discuss. In the past, surprisingly little consideration has been given to this subject. The literature on this subject consists almost entirely of anatomic descriptions of hearts that had ruptured following compression or contusion of the body. Only a few discussions on the clinical manifestations of cardiac contusion could be found, and it would seem that the surgical aspects of the subject have been almost entirely neglected.

One is accustomed to look on the heart as an organ that almost always escapes any of the ordinary injuries to which the rest of the body is subjected. The thoracic cage affords what is usually considered to be practically a perfect protection to the heart. No such immunity to injury is extended to the liver, spleen, kidneys, brain and other organs of the body. It is remarkable that this belief has developed, because the heart, lying against the sternum anteriorly, is vulnerable to any sudden impact over the sternum and, buttressed against the bodies of the thoracic vertebrae posteriorly, is vulnerable to compression forces applied to the chest. There can be little doubt that the heart is the recipient of many injuries. Most of these probably produce no functional disturbances and these are not recognized. Indeed, injuries that do produce functional disturbances are not recognized in the vast majority of instances.

The attitude of the profession toward cardiac contusions was expressed by THE JOURNAL as recently as Nov. 4, 1933. In that issue was published a query from a physician in Lincoln, Neb., as follows:^{2a}

A man, aged 57, was accidentally struck over the precordium by a golf ball. He was in a state of shock for fifteen minutes and gradually recovered so that he was able to attend to his business the following two days. On the night of the third day there was an attack of angina pectoris, with electrocardiographic evidence of cardiac infarctions. Prior to the chest injury there had been no symptoms of coronary disease. Is it likely that there was a traumatic myocarditis? Can you refer me to some literature bearing on this subject?

The answer was as follows:

Mild infections may predispose to a coronary thrombosis, as mild infection of the upper respiratory tract, mild cystitis or some minor ailment, and it is conceivable that the slight accident might have had some bearing on the coronary thrombosis. It is much more likely, however, that it was simply a coincidence.

Traumatic myocarditis is one of those indefinite terms that is best not used at all, and there is no literature of scientific value on the subject.

My interpretation of this incident differs from that quoted. I believe that the blow over the precordium by the golf ball bruised the heart. In spite of the infer-

From the Department of Surgery the Lakeside Hospital and the Western Reserve University School of Medicine.
Read before the Section on Surgery General and Abdominal at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

¹ Since this report has been made I have heard of so many probable cases of cardiac contusion that considerable doubt is thrown on the truth of this sentence.

^{2a} Relation of Myocarditis and Coronary Thrombosis to Trauma. Queries and Minor Notes. J. A. M. A. 101: 1503 (Nov. 4) 1933.

ence that the injury was a slight one, the force with which a golf ball can strike may be more than slight. However, it would seem that the force necessary to bruise the heart need not be severe. The ribs and sternum need not be broken and, indeed, the thoracic wall need show little or no evidence of trauma. The shock that developed after the accident could be explained on the basis of impaired function from the contusion. Also anginal pain is not uncommon in cardiac contusions, and the electrocardiogram produced by a myocardial contusion may be similar to that of a myocardial infarct.

I can give no further specific data in this case to support the diagnosis of myocardial contusion. Because the clinical manifestations of a myocardial infarct and a myocardial contusion may be similar, the differentiation becomes difficult, sometimes impossible. It would seem that the only essential differential point may be the trauma. Because trauma is so frequently irrelevant in the history of any medical lesion, one does not have much hesitation in considering trauma as a coincidence in the case of a cardiac lesion. A contusion of the heart would seem to be an excessively rare lesion, almost every one with whom I have discussed the subject never heard of it. Coronary disease, on the other hand, is a common lesion. To what degree cardiac contusions have been neglected clinically I can show by a statistical review of the literature.

Fig 1—The precordium is caved in. The heart is flattened out between this depressed area and the vertebrae. The patient has been a chronic cardiac invalid since the accident which occurred at the age of 4 years.

When the heart receives a contusion, one of three possible courses is taken. 1 The heart ruptures. 2 The heart fails without rupture. 3 Recovery takes place. The statistical study was made by Dr Ernest F Bright, who also collaborated with me in an experimental study of cardiac contusions.² The cases that were taken for this analysis consisted of the nonpenetrating forms of trauma to the heart. Cases that were complicated by rupture of a cardiac valve were excluded from our analysis. We excluded also cases that showed disease of the coronary arteries and in which there might have been some doubt as to the rôle of the trauma. Cases of heart strain were also excluded.

There were 152 instances of rupture into one or more of the cardiac chambers. The diagnosis in these cases was established by necropsy.

There were eleven instances of myocardial failure without rupture. The diagnosis in these cases was established by necropsy.

There were twelve instances of myocardial contusion in which recovery took place. The diagnosis in these cases with one exception (the case of Mansell Moullin, in which operation was done) was made by clinical manifestations.

According to these statistics it would appear that out of 175 patients with nonpenetrating wounds of the heart 152, or 87 per cent, died from rupture, eleven, or 6 per cent, died from myocardial failure and twelve, or 7 per cent, recovered. Obviously these proportions do not represent the correct relative incidence of these types of cases. There can be no doubt that 93 per cent of such cases are not fatal. The error is in the number of cases in which recovery occurs in which only a clinical diagnosis can be made. It would seem that clinicians hesitate to make the diagnosis of a cardiac contusion. They would like to have proof for such a diagnosis and there may be no proof. Contusions or nonpenetrating wounds of the heart rarely destroy life. The heart can tolerate an enormous amount of trauma and recover. On this point Dr Bright and I feel that we can speak with some authority.

We exposed the heart in a series of twenty-five experiments and applied contusive injuries to the myocardium. An area of the right or left ventricle was struck a number of blows with a metal instrument. The amount of trauma applied seemed to be excessive. The myocardium became swollen from hemorrhage and it looked as though softening and rupture would surely follow. These contusions were tolerated remarkably well in twenty of the twenty-five experiments. The immediate response was a tachycardia, occasionally, however, the pulse rate was decreased after the trauma was applied. The electrocardiogram showed changes similar to those obtained in coronary disease. The alterations affected chiefly the Q wave and the T wave, but the electrocardiogram usually returned to normal within three months. A hemorrhagic effusion not infrequently developed in the pericardial cavity. Usually the heart showed some dilatation after the trauma was applied. The cardiac sounds had a peculiar "tick tick" quality and tachycardia usually persisted for three weeks. Usually adhesions developed between the heart and the pericardium, and these adhesions may be interpreted as an attempt by nature to seal over the area of contusion and to protect the heart from rupture. The causes of death in the five experiments were rupture of the heart, ventricular fibrillation and cardiac failure from tachycardia. Rupture occurred in one experiment, and this was in response to an excessively severe trauma at the time the trauma was being applied. Ventricular fibrillation occurred in two experiments. This developed at the time the trauma was being applied, and at autopsy hemorrhage was found in the interventricular septum. Myocardial failure occurred in two experiments. In both of these experiments the heart rate was very rapid. Death occurred a few hours after the experiment in one and on the following day in the other. In none of these experiments did an aneurysm of the myocardium develop, but the experiments were terminated three months after the trauma was inflicted.

² Bright, E. F. and Beck, C. S. Nonpenetrating Wounds of the Heart. A Clinical and Experimental Study. *Am Heart J* to be published. We are indebted to Dr J. A. Groh for his assistance in the analysis of the German literature on this subject.

I cannot say whether an aneurysm would have developed if a longer period of time had been given.

One can conclude from these experiments that the heart can tolerate an excessive amount of trauma, that recovery is the rule rather than the exception, and that if death occurs it is caused by ventricular fibrillation, rupture or myocardial failure coming on after a tachycardia. Rupture is a rare complication of a cardiac contusion, nevertheless, the literature consists almost entirely of these rare cases of rupture. The vast majority

of the largest group of cases, cases in which recovery takes place, go by unrecognized.

On the basis of this analysis of cases I can give in outline form the mechanism by which non-penetrating wounds of the heart have been produced.

1 By a direct blow over the precordium producing fracture of the sternum and ribs, the broken ends of which are driven into the heart. A cavity of the heart may be penetrated, death taking place immediately, or

Fig 2—Anteroposterior view of heart which is enlarged. The deepest part of the depressed area is slightly more radiopaque than other parts of the heart.

the myocardium may be bruised. Delayed rupture may occur, cardiac failure may occur without rupture, an aneurysm may develop, recovery may take place.

2 By contusion or compression of the heart between the sternum anteriorly and the vertebrae posteriorly. This space is occupied almost entirely by the heart and any decrease in it directly affects the heart. The ribs and sternum may or may not be fractured. Rupture may take place without fracture of the thoracic wall.

3 By the application of indirect forces, such as by the sudden compression of the legs and abdomen. An extraordinary case was recorded by Kellert³ in which a man was engulfed to his waist in a sand bank. The heart and pericardium were ruptured. Dr Bright and I carried out an experimental study of this mechanism.⁴

4 By laceration of the thoracic viscera, such as may be sustained in a fall from a high building.

5 Concussion of the heart, a questionable type of injury so far as the heart is concerned. There are cases of vagus stimulation with stoppage of the heart in the literature.

The mechanism by which rupture of the heart takes place in nonpenetrating forms of trauma is as follows:

1 By bursting the heart when it is compressed between the vertebrae and the sternum, much as a toy balloon can be ruptured in one's hand. One would expect that a trauma of this nature would be more destructive if it should be applied at the end of diastole or at the beginning of systole, when the heart is filled with blood. One would also expect this trauma to be more destructive if it should be applied from the base of the heart toward the apex, so that the blood cannot escape as the heart is compressed.

2 By breaking the myocardium. Myocardium is of a friable nature. It can be broken. Even though the heart should be emptied of blood, the ventricular wall could be cracked or broken.

³ Kellert Ellis. Traumatic Rupture of the Heart. Report of a Case with Uninjured Chest Wall. *J. Lab. & Clin. Med.* 2:726 (July) 1917.

⁴ Beck, C. S. and Bright, E. F. Changes in the Heart and Pericardium Brought About by Compression of the Legs and Abdomen. *J. Thoracic Surg.* 2:616 (Aug.) 1933.

3 By contusion with subsequent softening. Our analysis of the cases showed that, if the patient survived the first nine hours, the probability of surviving the first week was better than the probability of surviving the second week. One would expect the greatest amount of softening of the myocardium to be present during the second week, and this point should be given special consideration in the treatment of these cases, so that such blowouts of the heart may be avoided.

4 By increasing the intracardiac pressure, as by the application of a compression force to the legs and abdomen in individuals in whom the heart has a decreased resistance to dilating forces.

REPORT OF CASES

Following is a brief summary of three cases in which I made a diagnosis of cardiac contusion.

CASE 1—A man, aged 68, a physician, admitted to the Lakeside Hospital in 1932, had been kicked on the chest by a colt at the age of 4 years. The sternum and ribs were caved in. He was unconscious for several days after the accident. He was kept in bed for six months, and when he left his bed he was unable to carry on the usual activities of a child his age. Throughout his life he could not run and play as did other children his age. The slightest exertion produced dyspnea and palpitation of the heart. He always had to restrict his activities. In 1929 cardiac decompensation developed, and since that time he has had to spend most of his time in bed. The deformity of the chest is shown in figure 1. The depression of the precordium was 6 cm in depth and on the periphery was 12 to 18 cm across. Roentgenograms showed the transverse diameter of the heart to be markedly increased and the distance between the sternum and the vertebrae to be greatly reduced (figs 2 and 3). Under the fluoroscope we found nothing that could be interpreted as an aneurysm. The electrocardiogram showed slurring of the QRS complex in all leads, slight depression of ST in leads I and II, slight elevation of ST in lead III, T in leads I and II upright, and T in lead III inverted. The electrocardiogram was interpreted by Dr Harold Feil as showing auricular fibrillation and myocardial damage. Obviously the heart was damaged in this accident. It is difficult to see how it could have escaped injury. That it was injured is indicated by the disturbance in function following the trauma. The heart appears as though flattened out between the vertebrae posteriorly and the depression anteriorly.

The question arises as to whether this flattening of the heart was a factor in disturbing its function and if so should this deformity have been corrected by operation. I am of the opinion that a deformity of this nature should have been corrected by operation done

at an early period after the accident before the fractures united. It is indeed remarkable that such mechanical disturbances to the circulation are so reluctantly brought into the surgical category. Mechanical deformities of other parts of the body are treated by mechanical methods, that is, by operation. Indeed, the mechanical deformities affecting the cerebrospinal fluid pathway, the gastro-intestinal tract, the biliary and urinary tracts comprise a large part of present-day surgery. But

Fig 3—Lateral view showing the heart lying between the depressed area of the precordium and the vertebrae.

mechanical disturbances to the heart as yet can scarcely claim a place in surgery. This development necessarily will take place and the time will come when exploratory pericardiotomy will not be an uncommon operation. The term "exploratory pericardiotomy" is greeted by physicians of today with a feeling of spontaneous disfavor.

CASE 2—This patient also was a physician. The diagnosis of a myocardial contusion may be open to some question in this case, but the symptoms referable to the heart clearly dated to a serious accident while the patient was serving in the army in France. These symptoms now consist of attacks of cardiac asthma brought on by exercise. Except for these attacks, the examination is essentially negative. The patient is now 59 years old. He was in perfect health until the night of his accident, which occurred Nov 22, 1918. He was riding on a motorcycle, all lights were out and he ran headlong into a heavily armored truck. Presumably the patient was thrown forward against the truck. Immediately he became dyspneic, he was carried to a hospital, he was unable to lie on his back because of severe pain in the chest. He was kept in bed until January 1. During this period he was subject to severe attacks of dyspnea and pain. These attacks persist to the present time. They are not so severe as they were years ago, but the patient brought on an attack by exercise so that I could observe it. After it

Fig. 4—The heart is compressed between the vertebrae posteriorly and the sternum anteriorly. This form of accident is not uncommon and may be referred to as the steering wheel injury.

came on it was a most awful spectacle. I thought the man might die as he labored for breath. The pulmonary aspects of the attack were more pronounced than the circulatory manifestations. The electrocardiogram taken during the attack showed nothing remarkable. Fluoroscopic examination of the heart was negative.

In this case, I believe, a contusion of the myocardium cannot be excluded as the cardiac abnormality which brought on the symptoms after the accident was sustained. The evidence to support the diagnosis of cardiac contusion in this case is meager. It is based on two facts. The patient was in excellent health and never had any cardiac symptoms prior to the accident. The second fact is that circulatory collapse developed immediately after this severe injury to the chest, and the symptoms that followed were those of cardiac asthma. Cardiac asthma develops in a variety of cardiac lesions and it is probable that a contusive type of injury could produce cardiac asthma.

In case 3 I feel secure in making the diagnosis because it was confirmed at necropsy.

CASE 3—A man aged 49 was injured by driving his car into the cement buttress of a bridge. He was thrown forward with his chest against the steering wheel (fig 4). He extricated himself from the wreck, got out and walked around the

car. He wanted to continue his journey but was persuaded to go to a hotel. He sustained fractures of several ribs. These were strapped and against his wishes the patient was placed in a hospital by Dr. Kenneth D. Smith of Marion, Ohio. He said he felt all right except for some pain from the fractures. On the third day after the accident, Dr. John S. Hattery of Mansfield was called to see him. At that time the patient had a rapid pulse and seemed to be seriously ill. I saw him on the fourth day. He showed a tinge of cyanosis, slight dyspnea, and a pulse rate of 136 per minute. Frequent premature ventricular contractions were present. The electrocardiogram showed evidence of myocardial injury (fig 5). The cardiac sounds were reduced in intensity and showed a peculiar "tick-tick" quality. These sounds were similar to the sounds in our experimental cardiac contusions and this peculiar quality helped me make the diagnosis of a cardiac contusion. The fourth, fifth and sixth ribs on the left were fractured. The sternum was slightly depressed and had a transverse fracture line in its lower third. There was no evidence of hemothorax, pneumothorax, pneumonia, or abdominal complication. I made the diagnosis of a myocardial contusion and advised absolute quiet. Because of the patient's attitude in minimizing the seriousness of his injuries he was told that he had a contusion of the heart, and the dangers were pointed out to him so that his cooperation might be secured. He was given morphine. He was not to make the slightest physical or mental exertion. Mild purgatives were to be given as needed so that there would be no straining. Coughing, sneezing, laughter and any movement that might increase the intracardiac pressure were to be avoided. Thirty-six hours after I saw the patient, he died from myocardial failure. The necropsy showed two contusions in the posterior wall of the right ventricle the size of a dime (18 mm) and a laceration of the myocardium between these areas. The heart had not ruptured. There were some old cardiopericardial adhesions, some coronary sclerosis and some fatty infiltration of the heart.

In this case the heart undoubtedly failed because of the contusion that it had received. The response to the contusion was similar to that which we observed experimentally. Had my attention not been directed toward this subject by the experimental work, I am doubtful whether I should have recognized it clinically in this patient. I have one criticism to make of the treatment. I, as the surgeon, should have remained in constant attendance, and the operating room should have been kept in constant readiness so that if the contusion had ruptured the fleeting opportunity to suture it might have been utilized. So far as I can find out from the literature, no such opportunity has ever been taken by a surgeon. In this particular case, however, the heart had not ruptured and operation was not indicated. But on the basis of present knowledge of this subject there seems to be no way of foretelling whether softening and rupture would or would not have taken place. A crack in the myocardium was present. It might have extended into the cavity of the heart later on if the patient had lived.

Tuohy and Berdez⁵ reported a case in which a similar accident brought about a myocardial contusion. Other instances of cardiac contusions have been reported by the Kahns.⁶ These authors discuss the difficult problem of diagnosis.

The cases of nonpenetrating wounds were analyzed from the point of view of treatment. Dr. Bright and I were particularly interested to determine whether or not this type of trauma held any promise for future surgical development. We analyzed the group of 152

⁵ Tuohy, E. L. and Berdez, G. Two Instances of Perforation of Heart Following Nonpenetrating Chest Injury. *Minnesota Med* 9: 144-146 (March) 1926.
⁶ Kahn, M. H. and Kahn, Samuel. Cardiovascular Lesions Following Injury to the Chest. *Ann Int Med* 2: 1013-1046 (April) 1929.

cases in which rupture of the heart had occurred. These patients all died from hemocardiac tamponade. Out of the group we selected only those cases in which at least forty-five minutes or an hour elapsed between injury and death. This should allow time for preparation for the operation. The other requirement placed on the cases of this special group was that the lesion in the heart was not so extensive but that surgical repair might have been feasible (fig 6). Out of the group of 152 cases we found thirty cases in which it would seem that operation offered some chance for success. In other words, about 20 per cent or more of the cases of cardiac contusions that go on to rupture should be placed in the surgical category. Operation has not been carried out in a single case of rupture. If our conclusion is correct on the point of operability, two questions present themselves: (1) when to operate and (2) what to do at the operation.

The question as to when operation should be carried out can be answered definitely. If there is a slow leak of blood into the pericardial cavity, a warning is given by the presence of the signs of increased intrapericardial pressure. A large rupture occurring suddenly gives only a few moments for the operation. The opportunity should be seized, heroic and instantaneous as the requirements of the operation may be. To take advantage of it means that the surgeon be in constant attendance and the operating room be in constant readiness for the operation. In some of the cases the hemorrhage is slow and the urgency is not so great. One operation was carried out in this group of nonpenetrating cardiac injuries. It was by Mansell Moullin on a young man

in whom a hemorrhagic effusion developed in the pericardial cavity following a trauma received in a football game. The pericardial cavity was opened and the fluid was evacuated. The patient recovered. In our experiments a hemorrhagic effusion was not infrequently found. We feel that the demonstration of a hemorrhagic effusion in the pericardial cavity demonstrated by aspiration may be helpful evidence in the diagnosis of this lesion.

The question as to what should be done at operation can be answered only on the basis of experiment. In most of the cases in our so-called oper-

ative group the ruptured wall was firm enough so that it could have taken sutures. In those cases in which areas of the myocardium are softened and which look as though they might again rupture after they are sutured, a graft of pericardium can be sutured over the contusion. This graft will reinforce the heart so that it can the better withstand the intracardiac pressure. This operation is being developed experimentally at the present time. It is my belief that it can be applied to nontraumatic cases also—cases of myocardial infarct and cases of spontaneous rupture in which the auricular⁷ or ventricular walls are pathologically weakened. Certainly it can be shown experimentally that a graft can reinforce an area of contusion in the heart. It remains for surgeons to look on the operation of exploratory pericardiotomy with greater favor. Why not try to control bleeding from the heart much as one would suture a tear in the liver or spleen? Why not reinforce a weakened ventricular or auricular wall by a fascial graft? There are problems to be overcome, both diagnostic and technical in nature, but these developments, I believe, will be made in the future.

Since this report was made, I have seen three additional cases in which the diagnosis of cardiac contusion seemed probable. One patient was a young man who sustained a steering wheel injury. Dr Wearn saw the boy immediately after the accident. For a few moments he was prostrate and the systolic pressure was 82 mm of mercury.

An hour later at the hospital the arterial pressure was normal. The electrocardiogram showed suggestive alterations in the T wave. There were no fractures. He had tenderness over the left third costal cartilage, which disappeared in a few days. Another patient had multiple fractures of ribs and other bones. He developed a pericardial friction rub and during a period of several weeks showed alterations in the electrocardiogram. The third patient, referred by Dr Hattery of Mansfield, Ohio, had a reverse steering wheel accident, i. e., the steering wheel was driven against the patient when a street car ran into his automobile. This patient was 32 years old and was in excellent health before the accident, which occurred in February 1934, but since the injury he has been incapacitated. He has a tender area over the precordium and on exercise he has precordial pain. He has auricular fibrillation but the electrocardiogram at the present time, ten months after the injury was sustained, does not show alterations in the T wave.

Fig 6—A nonpenetrating wound of the heart not associated with fracture of the sternum or ribs. There was a small slit like rupture in the anterior wall of the right ventricle. Through the rupture a bristle was passed and a portion of the ventricular wall was cut away to show that the injury opened the cavity of the ventricle. Undoubtedly in the future such wounds as this will be treated by operation. The myocardium usually is sufficiently firm to hold sutures. The area of contusion can be protected from rupture by grafting a segment of fascia or pericardium over the wound. This operation may find application also in cases of myocardial infarct in which the possibility of cardiac rupture exists. (Drawing from Ballance, Bradshaw, *Lecture on Surgery of the Heart*, London: Macmillan Company 1920.)

Fig 5—Electrocardiogram taken on fourth day after the accident. It shows normal sinus rhythm, left axis deviation and inversion of T in leads I and II. The inversion of T in leads I and II without digitalis therapy is significant of myocardial damage.

active group the ruptured wall was firm enough so that it could have taken sutures. In those cases in which areas of the myocardium are softened and which look as though they might again rupture after they are sutured, a graft of pericardium can be sutured over the contusion. This graft will reinforce the heart so that it can the

⁷ Clowe, G. M., Kellert, Ellis and Gorham, L. W. Rupture of the Right Auricle of the Heart. Case Report with Electrocardiographic and Postmortem Findings. *Am Heart J* 9: 324-332 (Feb.) 1934.

ABSTRACT OF DISCUSSION

DR. R. L. SANDERS, Memphis, Tenn. In Memphis, most cardiac wounds are of the penetrating type. Dr. Beck has called attention to the nonpenetrating wounds of the heart. I desire to emphasize the following points made by the author. First, contused wounds of the heart occur but have not been accorded the proper clinical significance. Second, the second and third weeks of the disease mark the stage of the greatest softening and weakening of the cardiac muscle and hence the clinical importance of rest and care to avoid rupture. In Memphis hospitals my associates and I have studied a large number of records but find no diagnosis of cardiac contusion although, considered in the newer light, a few of them might be so classified. The records from two of our large hospitals and one private clinic showed that in a total of 326,500 admissions there was not a single case of cardiac contusion recorded. There were ten penetrating wounds of the heart. A study of 133,000 cases showed a body contusion in 814, but none indexed as cardiac contusion. In another survey we found eleven cases that might be placed under Dr. Beck's classification and presented as at least suggestive. Two of them showed depressed fractures of the sternum and ribs, operations were later performed, and both patients died. Eight recovered spontaneously, thus emphasizing a point made by the author that the cardiac muscle can stand a great deal of trauma and still recover. Dr. Beck has given us something to think about. In a large majority of such cases there will be an economic and insurance compensation phase, necessitating caution in making the diagnosis. However, after careful consideration of the cases Dr. Beck has presented, the condition may be recognized as a clinical and pathologic entity.

DR. JOSEPH T. WEARN, Cleveland. Dr. Beck has called attention to something that we, as internists, have rarely diagnosed in the past. It seems that the clinical condition described by Dr. Beck is in a state of confusion similar to that which existed concerning coronary thrombosis previous to Dr. James B. Herrick's papers in 1912 and 1918. Until then the clinical diagnosis of coronary thrombosis or occlusion of the coronary artery was seldom made, although it was frequently demonstrated at autopsy. A man of 55 whose condition had been diagnosed as coronary occlusion recently entered my medical service. I talked with him with great care and found that he owned a furniture store. His so-called coronary occlusion began one day when he used an implement to take a chair off the top shelf, the chair dropped, striking him in the chest. He collapsed but presently recovered. A few days later he collapsed again, at which time he was ordered to bed and since then has been considered to have coronary occlusion with typical electrocardiographic signs, but I think he has a contused heart. Recently a man entered Lakeside Hospital (and Dr. Beck was good enough to call me to see him) who had been crushed against a wall by a bull. His sternum and nine ribs on the left side were fractured, so that each time he took a breath the entire chest caved in instead of expanding. He has been watched carefully by Dr. Beck. The patient was very sick, but now, after several weeks, he is doing nicely. It is important to keep these people at absolute rest in bed for a long time—that is, from four to six weeks—because the infarcted area softens and a sterile abscess results. During the time the leukocytes are removing the dead muscle, there are two thin walls on each side of the abscess and it is then that the heart ruptures.

Individuals Limping Along—There are many individuals limping along hampered by abnormal attitudes and moods, by feelings of inferiority and of jealousy, by a latent feeling of guilt or uncleanness, by the temptation to daydream and to indulge in the seductions of phantasy. Some of these persons never develop a cleancut mental disorder. They may rarely come to the physician for these specific symptoms. The physician may only indirectly become aware of them if the patient comes on account of dissatisfaction with life. To such patients the physician, interested in human nature appreciative of the underlying conflicts of human nature, may offer invaluable help.—Campbell C. Macfie. *Psychiatry from the Standpoint of the General Practitioner, Pennsylvania M. J.* 38:59 (Nov.) 1934.

ASCITES OCCURRING DURING JAUNDICE, WITH RECOVERY

REPORT OF A CASE

JACOB MEYER, MD

AND

AARON LEARNER, MD
CHICAGO

The occurrence of ascites in cases of catarrhal jaundice is rare. Bauer,¹ in a study of the problem of catarrhal jaundice, saw only two cases in an extensive experience, in which along with the symptoms of catarrhal jaundice there was definite ascites and subsequent recovery. Jones and Minot,² in a series of twenty-six cases of catarrhal jaundice, observed two cases in which, in addition to the jaundice, a pro-

Microscopic section of liver showing increase in fibroblasts, histiocytes and eosinophilic leukocytes and also cytoplasmic changes in the liver cells.

nounced ascites developed. One of these patients recovered, and at operation (cholecystectomy) the liver showed what appeared to be a cirrhosis. The second patient, who died, showed clinically an identical picture to that of the case in which the patient recovered. Weir³ reported five cases of jaundice with ascites not due to cirrhosis in which the prognosis was considered good. We report a case presenting many similarities to the cases referred to. Further, in our case, an exploratory laparotomy gave us an opportunity to study biopsy sections removed at operation.

REPORT OF CASE

H. F., a white man aged 40, a factory worker, admitted to the service of Dr. Solomon Strouse Feb. 8, 1931, and dis-

From the Medical Service and the Stomach Study Group, Michael Reese Hospital and the University of Illinois College of Medicine.

charged, May 12, 1931, had been in good health until one year before admission. During this year he had been under observation at the Maudslayi Clinic of Michael Reese Hospital because of pain in the stomach, which came on immediately after meals. This pain was relieved by soda and a light diet. There was no definite food relationship to the pain though fatty foods seemed to aggravate his complaints. The pain was not present at night. At times there was a feeling of fullness in the epigastrium and a complaint of belching but no nausea or vomiting. The patient never had a gallbladder colic. The appetite was good. He was prone to constipation. He complained of nocturia. Lately he had been feeling rather weak.

Three weeks before admission to the hospital the patient noticed that his skin was yellow and that this was becoming more marked. Shortly before and during the onset of the jaundice he felt ill, and he stated that he had a cold at that time. There were no other complaints. The patient had not observed the character of the stools or urine. On admission there were marked icterus and moderate tenderness in the epigastrium, more to the right side. The liver was 6 cm below the costal margin. The spleen was not palpable.

The icterus index on admission was 205. Two weeks after admission an edema of the lower extremity was noticed, and two days later there was definite ascites. The jaundice at this time was still present but had decreased in intensity. The icterus index was 183. Four weeks after admission the ascites and edema of the dependent parts were marked. The abdomen was tense. The scrotum also was markedly swollen. Repeated examination of the heart revealed no evidence of organic heart disease. The heart was normal to percussion. There were no murmurs. There was no evidence of fluid either in the pleural sacs or in the pericardium. The icterus index was now down to 93. The figures of the patient's weight further illustrate the amount of water retention. On admission the patient weighed 113 pounds (51 Kg.), and at the height of the ascites and edema the weight was 145 pounds (66 Kg.). The blood pressure was 122 systolic, 82 diastolic.

Laboratory examination revealed the following. The urine was positive for bile. The albumin reaction varied between negative and one plus from day to day. Occasionally there were a few white blood cells and a granular cast. The specific gravity varied from 1.030 to 1.006. The feces were clay colored.

Duodenal drainage was positive for bile. On one occasion *Giardia* was seen. An Ewald test meal revealed total acid 65 free 30, blood negative.

Blood count showed 4,100,000 red blood cells, 8,000 white blood cells, hemoglobin 70 per cent, a normal differential, and coagulation time seven minutes.

Chemical examination of the blood revealed sugar 57, 79, nonprotein nitrogen 33, 28, cholesterol 160.

The Van den Bergh reaction gave an immediate direct and an indirect positive test. The icterus index was 205, 202, 183, 93, 41, 21. The Wassermann reaction was negative.

Röntgen examination revealed the stomach of the orthotomic type, two fingerbreadths below the crest. The rugae were diffusely dilated. The appearance was suggestive of polyposis. The distended cap had a normal appearance. When partly empty it had an irregular, hazy appearance. There was some tenderness on pressure.

Primary gallbladder pictures were negative.

When ascites was noted, the patient was placed on the following regimen: bed rest, fluids restricted to 1,000 cc. daily, a soft diet, predominately carbohydrate with restriction of salt, salyrgan, one ampule every four days, later two ampules every four days, magnesium sulphate one-half ounce (15 Gm.) every morning. The fluid intake and output were measured.

The response to treatment as measured by water and weight loss was very satisfactory and after two weeks the patient had returned to approximately the admission weight of 115 pounds. The icterus index had now dropped to 41, at which level it remained. The patient presented moderate icterus, no demonstrable ascites and no enlargement of the spleen. Because the condition appeared stationary and in order to rule out a malignant condition, an exploratory laparotomy was performed. Spinal anesthesia was employed. The peritoneal cavity was dry. There were no tumors. The stomach was dilated and

thickened. The gallbladder was distended and somewhat edematous and was thickened, though not acutely inflamed. The common duct was dilated to the size of the index finger. Behind the common duct was a large gland the size of an almond. The liver was enlarged and engorged. The stomach was incised because of the roentgenologic diagnosis of gastric polyposis; the mucosa was reddened and edematous. There was no obstruction at the papilla of Vater and there were no stones.

The gallbladder was removed and drainage instituted. Biopsy sections were taken of the liver, stomach and lymph node.

Microscopic examination of a section of the liver revealed the preservation of the normal architecture. The liver cells were in distinct cords radiating from the central veins, which showed no dilatation. The walls of the central veins were moderately thin. The intra-acinus capillaries were collapsed but were readily discernible because of the large, swollen Kupffer cells which were present in increased number. The Kupffer cells stained well. The liver cells were large and swollen. The cytoplasm was pale staining and presented an appearance of variable sized rather fine pink granules lying in a gray matrix. The cytoplasmic changes as described were uniformly distributed through the acinus. Occasionally a liver cell was seen with one or more small vacuoles in the cytoplasm, without displacement of the nucleus. In general the nuclei stained well, showing a distinct nuclear wall, purplish granular basichromatin and a distinct nucleolus. Scattered through the field were liver cells with no obvious nucleus and others wherein the nucleus was very pale staining, almost completely obliterated. There was a delicate increased intra-acinus capillary fibrosis. The portal spaces were more prominent than normal, being variably enlarged. There was an increase in fibrous tissues and in this connective tissue there was an infiltration of a moderate number of lymphocytes, fibroblasts, histiocytes and a few eosinophilic leukocytes. The bile ducts and vessels of the portal spaces showed no pathologic changes.

The gallbladder wall was thickened and showed an increased fibrosis. The epithelium was to a considerable extent desquamated while the remaining epithelium, though staining well, was moderately swollen. Throughout the entire thickness of the wall there were seen an infiltration of lymphocytes, a few eosinophilic leukocytes and an increase in fibroblasts and histiocytes.

A section of the lymph node revealed obliteration of the normal architecture. There was hyperplasia of the reticulum cells, which were swollen and increased in number. There was an increased fibrosis. Scattered through the field were a small number of eosinophilic leukocytes.

A section of the pyloric portion of the stomach showed an intact epithelial lining. The mucosa was thickened. The tunica propria of the mucosa showed an infiltration of lymphocytes, plasma cells, eosinophilic leukocytes and a moderate number of macrophages.

The patient made an uneventful recovery, postoperative drainage, however, was maintained longer than usual. Two weeks after the operation the icterus index had come down to 21.

At present, approximately three and a half years after the onset, the patient, in excellent general condition, presents no signs of jaundice or ascites. Laboratory studies reveal a Van den Bergh direct negative and an indirect delayed positive reaction, the icteric index, hemolysis. The blood sugar is 63, nonprotein nitrogen, 42.

COMMENT

We have avoided the term "catarrhal jaundice" because this case presents an opportunity to examine more critically the relation between so-called catarrhal jaundice and the severer forms of liver damage.

Catarrhal jaundice was previously considered an ascending infection from the gastro-intestinal tract associated with a plugging of the common bile duct by the mucous swelling of the duodenum. Such a relatively simple conception has now been replaced by the

view of Rolleston and McNee⁴ that "most if not all cases are due to an infection involving the bile ducts and liver cells, that is to say, a combination of hepatitis and cholangitis." Klemperer and his associates⁵ on the other hand, "in view of the extreme variability existing in different cases of catarrhal jaundice," state that "this condition cannot be considered either as a morbid or pathologic entity." These authors divide catarrhal jaundice into three groups: 1 "Icterus due to obstruction of the ostium of the common duct, from gastro-intestinal catarrh. This is true catarrhal jaundice." 2 "Icterus due to degeneration of the liver with multiple necrosis. This is evidently hematogenous in origin and is Eppinger's acute yellow atrophy in miniature." 3 "Icterus due to cholangitis." Klemperer's observations parallel those of Eppinger. It is extremely interesting, in view of these opinions and observations on catarrhal jaundice, to correlate the observations of MacMahon⁶. In a recent review of infectious cirrhosis he says "Biliary cirrhosis is any cirrhosis of the liver originating from disease of the bile ducts or obstruction to the outflow of bile. Histologically the inflammation is localized in the portal areas, the cell types differing however, depending on whether we are dealing with an acute or a healing process. In the healing stage the infiltration consists of endothelial leukocytes and fibroblasts." It is obvious that the dividing line between a catarrhal jaundice and infectious cirrhosis cannot be definitely drawn. Our case showed definite evidence of gastro-intestinal inflammation and also of an infectious cirrhosis. The clinical features were those of a catarrhal jaundice during which ascites developed. These observations emphasize the fact that catarrhal jaundice cannot be considered a finely delineated entity but rather a functional disorder in which the underlying pathologic basis may be diverse.

The occurrence of ascites arouses interest in the relation of injury to liver to water metabolism. Injury to the liver is associated with a disturbance in water balance. Bauer¹ often observed evidence of water retention in catarrhal icterus, and he observed two cases with ascites. He considered the ascites a sign of liver atrophy. Adler⁷ also noted in jaundiced patients a reduction in water output. He made similar observations in patients suffering from liver disease without concomitant or only light jaundice. There is a direct relationship between liver function and the water metabolism, so that the dilution and concentration test may serve as a procedure in the study of liver function provided cardiac or renal factors can be eliminated. Pollitzer and Stolz⁸ reached the conclusion that in diffuse liver disease of the type exemplified by icterus catarrhalis there is a rise in the residual water content of the body, and a level of equilibrium reached that can pass into a condition of ascites as soon as that level is exceeded. Pozzi⁹ on observing in patients with liver disease the modification of diuresis under the action of merbaphen, found that the results secured point to a direct action of that diuretic on the liver. It is difficult however, to account how the effects of merbaphen and

salyrgan are brought about. Furthermore, the *modus operandi* of the liver in its regulatory role in water metabolism is not clearly explained, though explanations and experiments are offered by Adler, Molitor and Pick,¹⁰ Cori and Mautner¹¹ and others.¹² That the liver plays a role in water metabolism is not denied by observation, though as yet the explanations of the mechanism cannot be considered adequate. In fully developed cases of cirrhosis, portal obstruction dependent on progressive fibrosis has been demonstrated by McIndoe.¹³ The degree of fibrous tissue increase and cellular infiltration necessary to effect an ascites is difficult to say, though very likely this is a variable factor dependent in part on the functional integrity of the liver parenchyma and other factors that are not known.

SUMMARY

A case of ascites occurring during what is generally termed catarrhal jaundice went on to complete recovery after three years' observation. The case illustrates the difficulty of presenting a fixed syndrome for so-called catarrhal jaundice and directs attention to other functional alterations dependent on varying degrees of liver injury.

Clinical Notes, Suggestions and New Instruments

URTICARIA CAUSED BY COLD

ALFRED W. DUBBS, M.D., ALLENTOWN, PA.

In looking over the literature for methods of treatment and data on which to base a prognosis, I found that but few cases of urticaria due to cold have been reported in the English literature. Bray¹ found only thirty-seven cases reported in all the literature before 1931, the first of these being mentioned by Béhier² in discussing a paper on urticaria. It is of interest to note at this point that one of these thirty-seven, a case reported by Duke,³ is not an urticaria due to cold but one due to light. Since the appearance of Bray's article I have been able to find but one more case reported in the English literature, that by Weiss,⁴ although a few have appeared in other than English publications during this time.

In view of the apparent rarity of this condition I thought that it might not be amiss to add my case to the literature.

REPORT OF CASE

A white woman aged 62, came to my attention for the first time in August 1934 complaining of an itching and redness of the hands and exposed parts of the body that appeared usually in the morning on exposure to cold air or objects. She had noticed these cutaneous reactions for a period of two weeks preceding this visit and before that a mild tingling of the fingers had been noted under similar circumstances during one week in February of the same year but never prior to that time. Questioning revealed that a trip to market, being the first venture outdoors in the morning, would usually initiate an

attack of redness and itching of the face, neck and hands. Accompanying this, the patient would notice some dyspnea and palpitation, the latter being a noticeable feature only when walking very briskly. The whole attack never lasted more than five or ten minutes, and only on one or two occasions was a recurrence noted in the same day. At this time the patient also observed that if the hands were immersed in cold water or brought in contact with cold objects, as ice cubes or milk bottles, the fingers and palms would become a dusky, brownish red with swelling accompanied by itching and burning. Flexion of the phalangeal joints caused pain. When the attack was initiated by immersion in cold water a definite line of demarcation was noted. Wheals were produced at will on any part of the cutaneous surface by the application of such objects as ice cubes, frosted glasses and cold metal. They always corresponded in size and shape to the objects applied. At one time I observed a wheal measuring 6 by 4 inches (15 by 10 cm.) on the forearm that resulted from carrying a package of cold meat. These wheals had all the characteristics of the commonly observed types of urticaria, i. e. reddish or pinkish elevations of the skin accompanied by itching stinging, prickling and burning. The phenomena in this case are essentially cutaneous, for at no time have there been any subjective or objective manifestations in relation to the mucous membranes of the mouth or throat during the eating or drinking of cold foods or liquids.

The patient suffers from a chronic pharyngitis and a tubotympanitis accompanied by a progressive otosclerosis, also mild recurring attacks of arthritis involving the small joints of the fingers (atrophic or rheumatoid type). There is a complete absence of all other forms of allergic reaction.

The family history was negative for allergic disease.

The patient was 5 feet (152 cm.) in height and weighed 103½ pounds (47 Kg.). The hair tended to be dry. The eyes and nose were normal. The tympani were dull and retracted. The mouth and tongue were normal. The teeth were well cared for. The tonsils were embedded and apparently diseased. There was lymph follicular hyperplasia of the pharynx. The neck was normal. The lungs were clear. The heart was normal. The blood pressure was ordinarily 130 systolic, 75 diastolic and during an attack it has remained the same. The pulse was ordinarily 80, with no change during an attack. The abdomen was normal. The extremities were normal except for some spindle shaped deformity of the middle phalangeal joints. The skin has shown no sign of autographism.

Urine collected immediately after an attack was yellow, acid in reaction, with a specific gravity of 1.020, and negative for sugar, albumin and hemoglobin. Microscopic examination revealed nothing abnormal. Blood studies showed a hemoglobin of 90 per cent (Tallqvist), red cell count of 4,540,000 and white cell count of 5,950, with a differential of 59 per cent neutrophils, 3 per cent eosinophils, 30 per cent lymphocytes and 8 per cent monocytes. The bleeding time was two and one-half minutes, the clotting time one and one-half minutes. The blood was type IV (Moss). The Wassermann reaction was negative.

In an endeavor to demonstrate that these cutaneous reactions were due to a disturbance of the vasomotor mechanism, I at one time administered 5 minims (0.3 cc.) of epinephrine hydrochloride subcutaneously, with an almost immediate subsidence of all symptoms and signs. Subsequently calcium lactate in doses of 15 grains (1 Gm.) three times a day after meals has caused a marked reduction in the frequency and severity of the attacks. There has always been a complete recurrence following its withdrawal. Neither desensitization with histamine as recommended by Bray¹ nor autodesensitization of the French has been tried in this case. They are to be tried and the results together with other studies now in mind will be reported in a later communication.

I feel that this case is of interest because of (1) the apparent rarity of this type of urticaria, (2) the spontaneous appearance of such a type of sensitivity in a person of this age with no prior allergic history in self or family with the exception of an infectious type of arthritis, (3) the fact that the phenomenon is essentially a cutaneous one, and (4) the apparent response to calcium therapy.

138 North Eighth Street

OSTEITIS FIBROSA CYSTICA AND RENAL CALCULI WITHOUT HYPERCALCEMIA

CLARENCE L. ROBBINS, M.D., NEW HAVEN, CONN.

Recent contributions¹ to the subject of hyperparathyroidism have stressed the necessity to consider the entire clinical and laboratory picture of the disease rather than to place too much reliance on any isolated observation or group of observations. The so called metabolic criteria of hyperparathyroidism may be duplicated in conditions in which there is no evidence of hyperfunction of the parathyroids.² Likewise in proved cases of hyperparathyroidism the metabolic criteria may be absent. Gutman¹ has noted that, of seventy-eight reported cases of hyperparathyroidism in which determinations of serum calcium were recorded, 25 per cent failed to show a consistent hypercalcemia. This case of osteitis fibrosa cystica generalisata is reported as an instance of probable hyperparathyroidism fulfilling all the clinical and roentgenographic criteria of the condition with, nevertheless, consistently normal concentrations of calcium and phosphorus in the serum.

Mrs. M. C. was first admitted to the New Haven Hospital in 1922, when she was 48 years old, for nephrectomy on the right side because of renal calculi and pyelonephritis. At this time some rigidity and abnormal position of the right leg was noticed but was not investigated.

She was readmitted, May 30, 1933 for a fracture of the right femur. The fracture occurred without any fall when she put her weight on the leg in getting out of a car. For some

years the leg had become more and more stiff with what was called arthritis, until for six months prior to admission she had been forced to use crutches. In addition she had noticed bowing and rotation of the right arm for a year and a half. For some years she had been troubled with increasing nocturnal urinary frequency. Constipation for several years necessitated the habitual use of saline cathartics.

Generalized hypotonia of the muscles was a striking feature of the clinical examination. The patient was irritable, was uncooperative, and occasionally became quite irrational. There was a moderate leukocytosis and a well marked hyperchromic anemia but no abnormal cells in the spread. The urine contained some albumin but no Bence-Jones protein. Occasional red blood cells and granular casts appeared in the urine sediment, and numerous white blood cells were continuously present. The specific gravity never exceeded 1.010. When the first chemical examination of the blood was made, the patient was taking little food and was vomiting. The blood nonprotein nitrogen was considerably elevated and the phosphorus somewhat high. The phosphorus subsequently returned to normal but the nonprotein nitrogen remained elevated. The concentration of calcium in the serum was never above normal.

Roentgen examination revealed a fracture through the middle third of the femur with decalcification and multiple cysts in the distal fragment producing marked distortion of trabeculations and expansion of the cortex. Similar cysts and osteoporosis were present in the right radius. The skull was the site of spotty rarefaction and thickening, rather suggesting

From the Department of Internal Medicine Yale University School of Medicine.

² Robbins, C. L. and Kydd, D. M. A Note on the Metabolic Criteria of Hyperparathyroidism to be published.

Paget's disease. The twelfth thoracic and third lumbar vertebral bodies were markedly narrowed in their vertical diameters as the result of compression. An opaque shadow the size and shape of a hen's egg occupied the region of the left kidney pelvis.

Although the anemia did not respond to intensive liver therapy, the patient's general condition improved slightly and the fracture seemed to be healing well. Operation for parathyroid tumor was urged but the patient refused insisting on leaving the hospital. She died at home shortly after her discharge from the hospital on September 7. Autopsy was not secured.

In view of the osteoporosis, multiple cystic tumors and renal calcification, there can be little doubt of the diagnosis of hyperparathyroidism in this case, although the serum calcium was normal and anatomic evidence of parathyroid overgrowth is lacking.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING ARTICLE

HOWARD A. CARTER, Secretary

THERAPEUTIC EXERCISE

J. S. COULTER, M.D.

AND

C. O. MOLANDER, M.D.

CHICAGO

Therapeutic exercise may be defined as the use of scientifically supervised movements of the body, with or without apparatus, for the purpose of restoring diseased or injured tissues as near to normal function as it is possible. There are two types of therapeutic exercise—passive and active.

Passive exercise is that form of bodily movement which is carried through by the operator without the assistance or resistance of the patient. Mennell¹ uses the term relaxed movement. Relaxed movement should be administered with great care with the extremity placed in the correct position and properly supported. A pumping movement should be avoided. All relaxed movement should be well within the limit at which pain occurs.

The occurrence of a muscle spasm is a danger signal preceding pain. If such a protective spasm occurs, the movement should be stopped immediately. It should be kept constantly in mind also that one movement through its fullest range is much better than a series of movements through a shorter range.

The chief aims of relaxed movement are to maintain suppleness and to prevent contractures and the formation of definite adhesions. In this manner, passive exercise of muscles prepares them for active movement.

Stretching of contractures and old adhesions in chronic conditions should not be confused with relaxed movement. The object of stretching is to loosen contracted ligaments, muscles and adhesions in stiff joints and is to be used only after the inflammation of the joint has subsided. The technic of such a procedure should be a slow, steady and gradually increasing pull by the operator or with apparatus. The length of time applied and the amount of tension may be gradually increased, depending on the reaction of the patient. Joint soreness may be produced by such stretching, and a short application of heat with gentle massage will help materially in making the patient comfortable. As

a rule, any pain that passes off in an hour is not detrimental to the final success of the treatment. If there is an increase of swelling and pain or the range of motion is less the next day too much has been attempted. Splints may be used and a gentle pull maintained day and night. This should be increased gradually and kept constantly within the patient's capacity, otherwise, much pain and discomfort will be caused.

The angle of movement should always be recorded by using a goniometer and never estimated by the eye of the operator. Records of movement estimated by the eye of the operator are inaccurate and worthless. This is especially true when the stretching has been forceful. A design for making a goniometer may be obtained by writing to the secretary of the Council on Physical Therapy.

There is a highly beneficial maneuver that can be applied at this stage in the treatment. It cannot be classed under the heading of movement, because joint motion does not take place. The procedure is termed muscle setting and can be practiced by the patient while the leg or arm is in a splint. By it is meant the alternate contraction and relaxation of a muscle or group of muscles without movement of the joint. This type of exercise may be difficult for the patient to learn. It should be practiced under the watchful eye of the operator until the patient has accomplished it. Muscle setting is used in the early stages of acute traumatic injury or when it is impossible to obtain joint movement in chronic cases. Great benefit is derived by its use in restoring and maintaining muscle tone and strength.

Active exercise is one of the most valuable adjuncts available in the restoring of normal muscle function. It must, however, be properly applied and in gradually increased doses, depending on the reaction of the patient, in order to insure beneficial results. It should always be remembered that nerves and muscles are parts of a unit, the muscles having the power of contractility and producing motion, and the nerve having the power of irritability and conduction. If the muscle is properly rested and made to resume work gradually within functional limitations, it does not waste.

Active exercise is that form of bodily movement which is carried through by the patient, with or without the personal supervision of the operator, and is divided into assistive, free and resistive exercise.

Assistive exercise is that form of active exercise which the patient performs, assisted by the operator or some mechanical means such as a pulley and weight. Its chief objective is to enable the patient to accomplish more than he could do unassisted. This exercise calls for judgment on the part of the operator, who should aid only when the muscle is too weak to accomplish its movement. If fibrillation of muscles occurs, the muscles have been given too great a task and assistance is needed. However, when fibrillary contractions do occur, it is advisable to cease and obtain complete relaxation before treatment is resumed. The operator then will be able to give assistance at the right moment, thereby preventing further fibrillation. Progress must be watched carefully. The operator should increase the range of movement daily and should gradually develop the type of exercise from assistive to free.

Free exercise follows the assistive type and is defined as that form of active exercise which is carried through by the patient against the least possible resistance. To do this the body of the patient and the injured muscles are placed in such a position that gravity exerts no

¹ Mennell, J. B. *Massage Its Principles and Practice*. Philadelphia: P. Blakiston's Son & Co. 1920.

resistance to graded arc movements of the arm or leg to be manipulated. The range of movement should increase as the strength of the muscles increases and as adhesions are broken down.

True free movement is difficult to obtain and in reality the line of demarcation between free and assisted movement is not sharply defined. Free movement is obtained by eliminating the resistance of gravity and the resistance of friction. True free movement can be obtained by the "sling suspension" method, by placing the limb in a warm water bath or by the use of a smooth rectangular board, well powdered and placed so that the movement is in a horizontal plane. Each of these methods tends to reduce the friction to a minimum and produce truly free movement.

Resistive exercise is that form of active exercise, with or without apparatus, which offers resistance to muscle action. The resistance applied must be different for the different phases of the movement, least during the beginning and ending thirds, and greatest during the middle third or optimum of the muscle contraction. Correct resistance is often the only way to make one muscle group work alone and exclude its antagonists.²

No patient should be permitted or told merely to exercise his arm. It is the duty of every physician prescribing exercise to give definite directions as to the amount and kind. In the case of the patient with average intelligence, the anatomy of the part to be exercised and the reasons for the exercises should be explained to him.

In giving directions for exercises it should be impressed on the patient that, although heat, massage and electrical stimulation are used for his weak muscles, these are only to increase the circulation, and that nothing will increase muscle power but active exercise, which requires volitional effort on his part. To insure the proper regimen of treatment, definite written instructions for exercises should be given the patient.

Muscle reeducation is that form of therapeutic exercise which encourages voluntary muscular movements within functional limitations. It is given to muscles in which the neuromuscular coordination has in some way become partially destroyed. The reflex arc has become involved, making it impossible for the muscles to move by means of the reflex mechanism. As a result, coordinated movement is lost. To reeducate muscles under such conditions, two things are necessary: first, to reestablish a better coordination between the remaining nerve fibers and cells supplying the affected muscle; and, second, to secure the contraction of the desired muscle, however feeble.³

Mackenzie⁴ says that if a muscle is weakened or paralyzed, whether from injury of muscle, nerve or central cell, it is rested when its opponent is in a state of relaxation or elongation beyond the state normally regarded as necessary to produce a condition of equilibrium with its opponent. This is the zero position. Reeducation of a paralyzed muscle begins at zero and is the encouragement of voluntary muscle movements within functional limitations. The amount of work at this minimum may be slight, but it is the maximum function of the muscle at this time, and as such the muscle may soon become exhausted.

Curative occupational therapy is a form of therapeutic exercise that requires a series of specific volun-

tary movements, initiated by the patient which form component parts of a more complex and coordinated movement. This exercise is designed for the express purpose of securing definite end results and is a direct incentive for sustained effort.

The ordinary physical treatment given to a patient lasts, at the most, only an hour. The mechanical exercises given have certain definite limitations. The human body is more than a machine, and the mere formal repetition of a movement either with or without an apparatus is not of maximum therapeutic value in increasing the amount of movement in a stiff joint or as an integral part of a large coordinated movement. That is because there is no psychological stimulant for personal initiative or for sustained effort. The patient can be told to exercise, but unless occupational therapy is used there is no incentive and interest provided to continue the exercise. In physical therapy the patient's attention is focused on the injury, while in occupational therapy his interest is in the work.

THERAPEUTIC EXERCISE FOR THE SHOULDER JOINT

Mackenzie, in his classification of muscles moving the humerus, points out the important fact that the abductors of the shoulder joint are the relatively weak deltoid and the supraspinatus and that the adductor is the strong pectoralis major. The external rotators are the weak infraspinatus and the teres minor, while the internal rotators are the strong latissimus dorsi and the subscapularis. With this in mind, it is well in shoulder joint injuries requiring prolonged immobilization to put the arm in abduction and external rotation. This can be done in an airplane splint or in a plaster cast with the cover of the cast cut so that it can be raised. The muscle origin, insertion and action determine the splinting. Therefore if, after a shoulder joint injury, the arm is bound to the side, the anatomy, physiology and pathology are ignored. Too frequently this position is maintained for three weeks or more, with the strong muscles shortened and the weak ones stretched, and in addition the weight of the upper limb drags on the weakened deltoid.

A joint must be considered physiologically as a whole with no one component being injured without having an effect on the whole mechanism. It is necessary to understand the various movements of the shoulder joint and the extent of their range. It is to be understood that different individuals may differ with regard to extent of movement, and therefore it is always necessary to compare the injured side with the sound one. Beevor's classification for normal movement of the shoulder joint is given herewith.³

Flexion of the humerus. The arm is placed at the side and raised to front horizontal, and then above the head until vertical. This is the anteroposterior plane and produces an arc of 180 degrees the normal range for flexion.

Extension of the humerus. With the arm above the head in extreme flexion it is moved downward and forward to its original position at the side. This brings the arm through the same anteroposterior plane and the range is through the same 180 degree arc.

Hyperextension of the humerus. With the arm at the side, it is moved backward to the limit of movement through the same plane. The average degree of movement for this distance is 45 degrees.

Abduction of the humerus. With the arm at the side, it is carried laterally to a side horizontal position at a distance of 90 degrees. At this point the movement in the shoulder joint is stopped by the tension of the capsule. From then on the

² Buchholz, C. H. *Therapeutic Exercise and Massage* Philadelphia Lea & Febiger 1917

³ Jones and Lovett. *Orthopedic Surgery* ed 2 New York, William Wood & Co 1929

⁴ Mackenzie. *The Action of Muscles* ed 2 New York Paul B Hoeber Inc., 1930

movement is carried out by the scapula until it arrives in a vertical position above the head, covering a distance of 180 degrees

Adduction of the humerus The arm is again carried down through the same lateral plane, through the same number of degrees to the side of the body

Horizontal adduction and abduction The arm is placed in side horizontal position and is then brought forward to a front horizontal position. This is termed adduction and the arc range is 90 degrees, which is much extended by scapular movement. Abduction is the opposite of adduction through the same plane and a range of 90 degrees

Internal and external rotation The arm is abducted to a horizontal position, the elbow flexed and the forearm at right angles, which brings the shoulder joint in a position of external rotation. Bringing the forearm forward and downward produces internal rotation. The arc is 90 degrees in this plane. With the arm in partial abduction and the forearm extended, the degree of rotation is increased to 135 degrees

It is important to note here that the scapula takes part in practically all movements. The determination of the actual range of shoulder movements is difficult and inaccurate. As the mobility of the scapula is highly variable, all angular movements in and about the shoulder joint must be necessarily approximate

After the range and strength of the muscles of the shoulder have been increased in all planes because of the carefully regulated assistive, free and resistive exercises, the patient is taught a series of exercises for home use. The following list is suggested. The particular exercises to be used should be underlined. The number of times each movement is to be used must be indicated. We have found it advisable to have a mimeographed sheet of exercises for each joint

EXERCISES FOR THE SHOULDER

1 While the shoulder is in the splint, contract the deltoid and then relax without moving the shoulder joint or using other muscles

2 While the patient lies on the back, the arm and shoulder on a powdered cardboard, in the same position as in the airplane splint, the operator supports the forearm and adducts the arm a few degrees, and the patient returns it to the original position. Gradually increase the range of motion

3 Same position as No. 2. Revolve the forearm until the back of the hand touches the table

4 Same position as No. 2. Move the arm across the body so that the hand touches the opposite shoulder

5 Lying on the back, with the arm at the side and the elbow bent to a right angle, bring the arm forward and up and return

6 Lying face down, the hands in back of the neck.
(a) Raise both elbows from the table without raising the body.
(b) Raise the elbows with some one putting pressure on the elbows

7 Standing with the arms at the side, raise to the front horizontal position and then above the head and return

8 Standing, with the hands clasped behind the back, fingers interlocked, the palms facing up, turn the palms in and down, and extend the arms to the rear at the same time

9 Standing, with the hands at the side, raise the arms to the side horizontal position and then above the head and return

10 Standing, with the arms in the front horizontal position, raise to the side horizontal position, to the front horizontal position and return to the original position

11 Shrug the shoulders

12 Standing, with the arms in the side horizontal position, move the arms in small and large circles and in both directions

13 With the arms in the side horizontal position, rotate the arms so that the palms are alternately up and down

As the strength of the patient increases, resistance can be added with books or dumb-bells, starting with light weight and increasing the weight as the capacity of the patient increases

For assistive and active shoulder joint exercises, we use stall bars, a shoulder abduction ladder and weights and pulleys. Construction plans will be supplied on request

Curative occupational therapy for shoulder cases should be definitely prescribed. It can be used in any place with a little ingenuity. For instance, "braid weave" rug weaving may be used. No shuttle or beater is necessary and no sewing is required. The method does not require a complicated loom. The weaving, partaking somewhat of basketry, is fascinating and simple

The loom can be home made. It is 30 by 50 inches, made of $1\frac{1}{2}$ by $\frac{3}{4}$ inch wood. A series of $\frac{1}{4}$ inch slits at the top and bottom half an inch apart accommodate the warp. Along the inside $\frac{1}{2}$ inch from the inside edge of the loom are brass $\frac{1}{4}$ inch curtain rods to hold the weaving in perfect alignment and to insure a straight edge to the rug. The weaving is done with rags, which may be colored and a pattern followed. These looms may be made in various sizes and placed in various positions to conform with the patient's strength and to the joint movements required. By placing the loom high on a wall shoulder flexion, external rotation and abduction of the shoulder may be obtained. These looms may of course be purchased complete. After proper instruction, the patient can use this loom at home

(To be continued)

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER Secretary

SANBORN MOTOR-GRAFIC METABOLISM TESTER ACCEPTABLE

The Sanborn Motor-Grafic Metabolism Tester is manufactured by the Sanborn Company, Cambridge, Mass.

In principle, the Sanborn Motor-Grafic Metabolism Tester is a closed circuit, wet spirometer metabolism apparatus. Its appearance is good, and it is constructed so that it is convenient for use. The size of the instrument is 17 by 10 by 22 inches and the carrying weight is 35 pounds. It is equipped with a counterweighted oxygen bell of 6 liters, enough gas for an eight to ten minute test, operating in water-seal. There are two breathing tubes one for inhalation and one for exhalation, and it is equipped with either an alternating or a direct current motor directly connected to the blower, which circulates the oxygen through soda lime and breathing tubes. There is a quart and a half container holding soda lime for absorbing carbon dioxide. There is a permanent point metal stylus (a capillary pen cup is also supplied if desired) for graphically tracing the actual oxygen consumption with an electric clock mechanism for turning the chart record of tracing, once in eight minutes on 110-120 volts, 60 cycle alternating current, or a spring clock mechanism for turning the chart on direct current. There is also an adjustable breathing tube support with two-way oxygen control valve and thermometer attached to apparatus to show temperature of oxygen.

The unit is supplied complete with a metabolism barometer, an 80 gallon oxygen tank, a metal minor leak tester, enough soda lime for from forty to sixty tests, 100 stylograf charts,

three rubber mouthpieces, one nose clip, an extra capillary pen tube one way valves to be used when no electric current is available, a cover for the Motor-Grafic, and an instruction booklet with all metabolism "normals" and tables. The table supplied for the Motor-Grafic has a metal base with a wooden top (five ply), measures 15 by 20 by 28 inches has a holder for the oxygen tank, and is quietly movable on rubber-tired casters.

The estimation of metabolism is derived from a measurement of the volume of oxygen consumed during a given period of time. The consumption of oxygen is measured by a water spirometer and is recorded on the cylinder rotated at a known uniform rate. The determination is started with the spirometer containing an unknown volume of air rich in oxygen. It is allowed to run until the slope recording the consumption of oxygen is constant and well defined. Since the volumic thrust of the spirometer is known, as well as the rate at which the graphic cylinder is rotated, the rate of oxygen consumption can be determined from the slope. A cubic centimeter scale provided with the apparatus gives values in terms of cubic centimeters of oxygen consumed per minute when applied to the drop of the slope line in eight minutes. The apparatus is calibrated to include corrections for water vapor (2 per cent) for temperature at 21 C, at an atmospheric pressure of 760 mm. Corrections must be made for any deviations of temperature and pressure prevailing at the time of the test, to obtain values under standard conditions, viz, 0 C. and 760 mm. These corrections are made by reference either to the tables or to the graphs supplied with the apparatus and give the cubic centimeters of oxygen consumed per minute under standard conditions of temperature and pressure. The normal rate of oxygen

Sanborn Motor
Grafic Metabolism
Tester

consumption for a subject of known weight, height and age is also obtained from standard tables provided with the apparatus. Knowing both the actual and the normal rate of oxygen consumption, one can readily determine the comparative basal metabolic rate.

Technical errors in the determination are detected by noting any irregularities in the slope of the graph. Leakage from the nose and throat can be detected by the highly polished detector provided.

The Sanborn Motor-Grafic is designed for use in office practice and in the hospital, where it is quietly and easily movable on the mobile table supplied as part of the complete equipment. The manufacturer claims that the unit is conveniently portable and carried to a patient's home for bedside testing. Before it is moved however, the apparatus must be emptied of water and filled every time it is transported. In addition to this, the unit is quite heavy and cumbersome and also the oxygen tank, which is not light, must be taken along.

The Sanborn Company claims that this machine is useful in the field of metabolism testing. The place of metabolism testing in differential diagnosis, in the regulating of thyroid therapy, and in preoperative and postoperative management of goiter cases is well known and has been demonstrated by physicians and surgeons during the past fifteen years in office practice and in hospitals. The manufacturer claims that the Sanborn Motor-Grafic enables physicians to obtain the guidance of basal metabolism test reports by a method that is simple for the operator, comfortable for the patient and reliable for accuracy and dependability of results.

In a clinic acceptable to the Council, a number of determinations of metabolism by means of this apparatus were made on different individuals under various conditions and have given values that were essentially correct for normal, supernormal and infranormal metabolism. The therapeutic claim for the Sanborn Motor-Grafic "that it enables doctors to obtain the guidance of basal metabolism test reports by a method that is simple for the operator and reliable for accuracy and dependability" is warranted. As regards the claim that this apparatus "is comfortable for the patient," it may be stated that it is exactly as comfortable or as uncomfortable as all other appa-

ratus that requires the patient to wear a nose clip and breathe through a mouthpiece.

In view of the favorable report presented, the Council on Physical Therapy voted to include the Sanborn Motor-Grafic Metabolism Tester in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

AMYTAL (See New and Nonofficial Remedies, 1934, p 90)

The following dosage form has been accepted

Tablets Amytal $\frac{1}{4}$ grain

SODIUM AMYTAL (See New and Nonofficial Remedies, 1934, p 102)

The following dosage form has been accepted

Ampule Sodium Amytal 0.065 Gm (1 grain)

REPORT OF THE COUNCIL

THE COUNCIL AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
PAUL NICHOLAS LEECH, Secretary

ADRENAL CORTEX EXTRACT

At the instance of a commercial firm which contemplates the marketing of an extract of the adrenal cortex, the Council considered the matter of a name for an extract containing the hormone of the adrenal cortex and of a name for the hormone itself.

After a consideration of the several names suggested for the extract containing the hormone, and for the hormone itself, the Council decided that it would be advisable at this time to adopt a generally descriptive nonproprietary name for the more or less crude extracts and to defer until later the consideration of a name for the active isolated principle. The Council therefore adopted the title "Adrenal Cortex Extract" (with the Latin synonym "Extractum Adrenali Corticis"), as its nonproprietary name for extractive preparations from the adrenal gland that contain the cortical hormone necessary for life.

CEVITAMIC ACID AND THE BRAND CEBIONE—MERCK

Under the name "Ascorbic Acid" Merck & Company, Inc., presented for the Council's consideration its preparation of the crystalline vitamin C isolated by Szent-Gyorgyi. The product is marketed in the form of tablets each containing 0.01 Gm of the acid. By reason of its rules against therapeutically suggestive names the Council could not recognize the name "Ascorbic Acid" although this term has been used in the literature. The firm asked consideration of the term "Cebion" as a proprietary brand name for its preparation. The Council voted to recognize the name "Cebion" for the firm's product if it could prove its right to a proprietary name. Meanwhile the Council adopted the term "Ce-vi-tam-ic Acid" as a nonproprietary designation for the crystalline vitamin C introduced as Ascorbic Acid. Merck & Company, Inc. then presented written permission from Szent-Gyorgyi for the use of its proprietary name "Cebion" and in accordance with its rules and previous decisions the Council voted to recognize this as the proprietary name for the Merck brand of cevitic acid in recognition of the discoverer and of the service of the firm in making the product available for therapeutic use.

The Council feels strongly that investigators in naming newly discovered medicinal substances should bear in mind the fundamentally sound objections to the use of therapeutically suggestive names.

SATURDAY, JANUARY 12, 1935

THE PRESIDENT'S PLANS FOR ECONOMIC SECURITY

With all other American citizens, the medical profession awaited eagerly the message which the President of the United States delivered, January 4, to the joint session of the Senate and the House of Representatives. In spite of the obvious impossibility of absolutely definite statements because of the very nature of our government, the President, nevertheless, provided an indication of the character of the program contemplated in relationship to economic security. His plans seem to provide for the provision of work to many of the unemployed, the projects including such matters as slum clearing, reforestation and elimination of grade crossings, as well as many local projects. All of these have, of course, a definite interest for the medical profession. In fact, the housing projects and the elimination of the grade crossings must inevitably have a definite effect on morbidity and mortality rates.

Of special interest to the medical profession, however, were those paragraphs of his address in which the President referred particularly to questions of sickness and related problems. Thus he said:

Closely related to the broad problem of livelihood is that of security against the major hazards of life. Here also a comprehensive survey of what has been attempted or accomplished in many nations and in many states proves to me that the time has come for action by the national government. I shall send to you in a few days definite recommendations based on these studies. These recommendations will cover the broad subjects of unemployment insurance and old age insurance, of benefits for children for mothers, for the handicapped, for maternity care, and for other aspects of dependency and illness where a beginning can be made.

It is perhaps unwise to analyze too closely the significance of this statement. Interesting, however, is the manner in which the President passed immediately from unemployment insurance and old age insurance to the question of benefits for children, for mothers, for the handicapped and for maternity care, leaving the question of sickness insurance to the phrase in which he says "for other aspects of dependency and illness where a beginning can be made." The element

of time in relationship to the development of any definite plans of sickness insurance is of the utmost significance. There seem to be indications that the difficulties involved in developing schemes for providing persons in the lower wage levels with adequate medical care and at the same time preserving the quality of medical service and the integrity of the medical profession are far greater than they seemed to be at first glance to those who urged precipitate action. Innumerable experiments are now going on in many communities under local, industrial and similar auspices, including those conducted by county medical societies. Time has not yet permitted a real evaluation of their worth, yet their multiplicity is an indication of the extent and the complexity of the situation. Moreover, the employment of considerable numbers of people now unemployed and the establishment of unemployment insurance, old age pensions and the other factors mentioned in the program of social security will modify greatly the features of any plan for sickness care that may be developed.

The number of competent minds that have already been brought to bear on the solution of this problem should eventually yield at least a suitable experiment if not a complete solution. More than anything else the medical profession fears hasty action and the setting up of some scheme which, once established, will ride, like the old man of the sea, on the back of medical progress and impede its advancement. We have already witnessed the spectacle of hastily devised programs in foreign countries now undergoing constant repair. Eventually there must be some solution that will adequately serve the people and at the same time not sap the life blood of the medical profession.

THE FOOD AND DRUGS ACT REVISION

Under Association News in this issue appear statements, issued by the Council on Pharmacy and Chemistry and the Committee on Foods of the American Medical Association and endorsed by the Board of Trustees, relative to certain necessary revisions of the Food and Drugs Act in order to bring such legislation into accord with modern points of view. Some thirty years has passed since the law under which we now function first became effective. During that period there have been notable advances in the development of new types of pharmaceuticals and modifications of foods. Moreover, the administration of the measure under the Food and Drug Administration has yielded an experience that indicates quite definitely many ways in which the effectiveness of the work may be improved, as well as certain loopholes that need to be closed to the evader.

A significant feature of modern living is the development of advertising along lines never even contemplated in 1905. For example, we have seen since that time the tremendous development of great advertising agen-

cies, the use of the radio in advertising, and many other new forms of approach to public interest. Thus the chief emphasis to be placed on any new legislation must concern some type of control over advertising and promotion. People are being more and more informed relative to the nature of foods and drugs and the physiology of the human body. The intelligent purchaser wants to know the significant constituents and ingredients of products that may be taken into the body. Hence new legislation must demand suitable declaration on the labels of the significant ingredients of such preparations.

The advance in our knowledge of nutrition has brought into the situation the application of various special foods for the control of nutritional disorders known as deficiency diseases. This possibility has stimulated many exploiters to the promotion of food substances as medicaments. Any new legislation must take cognizance of the use of names of diseases on the labels of food products and thus avoid the danger of self prescription, which must be disastrous to human health. Nevertheless, the desirability of manufacture and promotion of foods for special purposes, as in conditions largely treated by diet (for example, obesity and diabetes) emphasizes the necessity for recognition of such special-purpose foods and the importance of suitable regulation over their manufacture and promotion.

Most significant also in relationship to new legislation is the placing of responsibility for failure to observe the new restrictions. It should be clear at once that publishers, as such, owners of radio broadcasting stations and others who are primarily in the business of advertising cannot be primarily responsible for exaggerated or untruthful claims made by the firms which they represent. Responsibility for advertising must rest ultimately with the individual or firm issuing the products.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION offers these suggestions to the legislators who are now concerned with the consideration of new legislation in these fields. The successful enactment of such legislation will yield incalculable good for the health of the American people as well as an immense saving to their pocketbooks.

LICE AND HISTORY

THE JOURNAL has commented frequently on the relationships between climatic factors and the spread of disease. The manner in which epidemics and wars influence the history of the world has been recounted in various publications. Quite recently, agitation has developed concerning the possibility of the spread of epidemics by means of air travel. The subject has been reviewed by Massey,¹ who indicates the way in which

the mosquito may be carried from country to country by airplane travel. Moreover, he has emphasized the possibility that cholera, plague, malaria, typhus and relapsing fever might be disseminated through the airplane, provided the vermin associated with their spread are carried either on the passenger or in other ways in air traffic.

In a forthcoming book entitled "Rats, Lice and History," Dr. Hans Zinsser,² professor of bacteriology and immunology in Harvard University, considers the manner in which the louse, the rat and the pestilences that they carry have influenced the history of the world. A preliminary chapter from this book appears in the *Atlantic Monthly* for January. Here Dr. Zinsser traces the evolution of the louse from the earliest types to the extraordinary varieties that inhabit the bodies of man, beast and fowl in these modern days. It would seem that the human head louse first made its appearance on the heads of primitive savages, coming from fur-bearing animals. Occasionally a head louse may breed with a body louse. The crab louse is of a different order. Once established on the heads of the savages, the louse seems to have passed from race to race, acquiring changes of form and feature in the process. Thus the lice of various races differ, that of the African being slightly different from the European and American types. It is interesting to know that lice have been found on mummies of early American Indians and Peruvians, and that the lice of the prehistoric Indians differ from those found on Indians living today. Apparently the louse has been the inseparable companion of man since the earliest times. Man is its only habitat and, if its host perishes, the louse is doomed unless it can promptly find another.

Until colonial times, lice were considered practically a necessity for the life and health of man. Then came the period that involved the development of the bathtub and a new order of cleanliness. "The louse is confined," says Zinsser, "in consequence to the increasingly diminishing population of civilized countries who live in distress and great poverty." He believes the louse will never be completely exterminated and that there will always be occasions when it will spread widely to large sections of even the most highly sanitized populations.

While this subject may not seem to be one that would inspire an extraordinary type of literary endeavor, the essay by Zinsser is a model of literary quality which may well afford inspiration to other contributors to the literature of medicine. The article provides a fine display of diction, it proceeds in an orderly manner, and the philosophical comments of the author, revealed with sly humor, keep one's interest constantly at a high point. The reader may acquire much scientific information with a minimum amount of difficulty and a maximum amount of pleasure.

BODY BUILD AND RESTRICTED GROWTH

In a recent communication, Bakwin, Bakwin and Milgram¹ have described the results of studies designed to determine the relationship between retarded growth and the so-called body build in young human subjects. An extensive literature is available pertaining to the manifold results of restricting development in experimental animals, adjustment of the diet in any one of several ways to bring about retardation of growth is uniformly followed by differential rates of growth of various parts of the body, resulting in distortion of the normal proportions.² One of the features of this atypical development is the persistence of growth shown by the skeleton, notably by the long bones. This phenomenon was early noted by animal husbandrymen, the narrow chests resulting from disproportionate growth in length by the ribs and the "rangy" (long legged) appearance of poorly fed cattle are well known results of chronic undernutrition. The possibility of the production of similar structural alterations in human subjects under conditions of malnutrition encountered in practice and also the significance of this factor in influencing body build are questions of considerable practical importance.

In approaching the problem, Bakwin and his co-workers made use of three large groups of infants. One, from a well baby clinic, served as a control, the second and third groups were from a poverty stricken environment, the second, however, being the subject of study in a health clinic under favorable nutritive environment. In addition to body weight and length, there were recorded two lateral dimensions of the face, the circumference of the thorax and the diameter of the trunk at two levels. At the end of the first year the two groups that were supervised showed little difference either in body weight attained or in the rate of gain, whereas the third group showed a marked delay in gain in weight. For the first three weeks there was little if any difference between the three groups in any of the linear measurements. At the end of the year, however, the supervised groups were superior to the underprivileged group to a greater or less extent in respect to the ratio of lateral measurements to body length. From a comparison of rate of increase of the various dimensions of the three groups of infants, two important tendencies stand out. The delay in growth shown by the third group took place entirely in the first three months of life, thereafter there is evident little if any difference between the groups in respect to rate of change in body weight or in other dimensions. Furthermore, the retardation in development in body length is of smaller magnitude than is that in the other measurements studied.

The results of the comparative studies on infants indicate that the human subject responds to early

unfavorable environment much the same as do experimental animals, so far as correlated changes in structure are concerned. There is also the implication from the New York studies that subtle factors, not always viewed with apprehension, may exert far reaching effects on groups of people—extensive enough, probably, to alter national types of population.

TIME FOR PAYMENT OF ANNUAL DUES

Since Fellowship and subscription dues are payable in advance, the usual colored reminder slip is enclosed in this issue of THE JOURNAL. Already many Fellows and subscribers have made the 1935 payment. Those who have not remitted will find the colored slip convenient, since it combines a statement and return envelop in the one form. No addressing or postage stamps are required. A remarkable series of articles by noted authorities on "Glandular Physiology and Therapy," defining the present status of our knowledge, is about to start in THE JOURNAL. Every physician should remit promptly and obviate any interruption in subscription service. A list of the special journals published by the Association appears on the statement-envelop form. These journals came into being as the result of requests by specialists in the fields they cover. General practitioners will find in them a stimulating reflection of progress in the respective specialties and answers to many of their problems. All Fellows and subscribers to THE JOURNAL are invited to take advantage of this service rendered by the Association and subscribe at the same time for any of the special journals in which they are particularly interested.

THE RETENTION OF NICKEL IN PSORIASIS

During the last few years, frequent references have been made to observations implicating certain of the metallic elements in disease processes. Recent studies¹ on dermal biopsy specimens taken from lesions in typical cases of psoriasis suggest that the metal nickel may be related to this condition. Quantitative spectroscopic analyses demonstrated that in nearly all the samples from normal control subjects nickel was absent, whereas it was present in all the specimens from patients with this disease. The few normal samples in which nickel was present contained less than 0.01 mg to each 25 mg of tissue, while the specimens from psoriatic lesions contained from 0.01 to 0.09 mg in the same size sample. From these data it appears that there occurs a significant local retention of nickel in psoriatic lesions. The full significance of the foregoing observation is as yet a matter of conjecture. It has been stated that individuals unduly exposed to nickel appear to be peculiarly susceptible to certain skin diseases and that opportunities for the entrance of traces of nickel

1. Bakwin, Harry, Bakwin, Ruth M. and Milgram, Lillian. Body Build in Infants. *Am. J. Dis. Child.* 48: 1030 (Nov.) 1934.
2. Smith, A. H. Edit. *Rev. J. Nutrition* 4: 427 (Sept.) 1931.

into the average normal subject are by no means rare. There is a ubiquitous distribution of nickel in plants, in soils and in foods. Also traces of this element may be derived from milk, catalytically hydrogenated fat water pipes, cooking utensils, and certain appliances used in the preparation of foods. At the present time, however, no evidence is available definitely establishing nickel as a causative agent in diseases of the skin. Further investigations such as the one just described on the quantitative composition of pathologic tissues should yield information of value in elucidating the etiology of certain diseases of obscure origin.

Association News

NEW FOOD AND DRUGS LEGISLATION

The Council on Pharmacy and Chemistry and the Committee on Foods of the American Medical Association have adopted respective statements concerning the revision of the Food and Drugs Act. These statements in turn have been endorsed by the Board of Trustees. Publication has been authorized by the Council, the Committee and the Board.

AUSTIN A. HAYDEN,
Secretary of the Board of Trustees

PALL NICHOLAS LEECH
Secretary of the Council on
Pharmacy and Chemistry

RAYMOND HERTWIG,
Secretary of the Committee on Foods

Report of the Council on Pharmacy and Chemistry on Revision of the Food and Drugs Act in Special Reference to Drugs

In the thirty years since the federal Food and Drugs Act became law there have been notable developments in scientific, technologic and economic fields and many changes in methods of manufacture, distribution and sale of drugs and drug products. Experience in the administration of the act has brought to light various ways in which the law is inadequate to meet modern conditions. To the end that public health and safety shall be better safeguarded in the matter of the manufacture, distribution and sale of drugs and related products it is important that the provisions of the present law be revised and its scope enlarged.

The Council on Pharmacy and Chemistry of the American Medical Association therefore deems it desirable that the law be amended (or a new law be made)

1 To include provisions for so regulating all forms of drug advertising that it shall be truthful in statement and not deceptive by implication, the terms 'advertising' to include all ways and means of bringing articles to the attention of the public for commercial purposes

2 To provide that responsibility for advertising rest with the individual or firm issuing it unless such individual or firm produces a guaranty as to the truthfulness of the advertising claims, and the guarantor is amenable to the terms of the act, in which case the guarantor shall be responsible

3 To provide that the active ingredients and the amounts or proportions thereof in all mixed drug products not listed in official compendiums (U S P and N F) be disclosed on the labels of such products and in the advertising of them

4 To prohibit the sale of drugs and drug preparations under names recognized in official compendiums (U S P and N F), unless such drugs and drug preparations meet the standards and specifications laid down in such compendiums

5 To require suitable declaration on labels and in advertising of any and all habit-forming drugs, whether sold singly or in mixtures, together with explicit warning that such may be habit forming provided that such declaration be not required in the

case of drugs or mixtures of drugs dispensed on prescription, and which are to be used according to directions of a physician

6 To provide for official announcement by the government of such drugs as may now be held, or in the future be determined, to be habit forming

7 To prohibit the mention of disease names on the label of drugs or drug preparations, or in advertising thereof unless such drug or drug preparation is a cure for the disease named, or unless such drug or drug preparation is a palliative and the nature of the palliative action is stated

8 To extend the provisions of the law to include cosmetics and the advertising thereof, the term 'cosmetics' to include all substances and preparations intended for cleansing, altering the appearance or promoting the attractiveness of the person, unmedicated soaps excepted

9 To extend the scope of the term 'drug' to include devices, substances and preparations intended for the treatment of disease and all devices and all substances and preparations other than food, intended to affect the structure or any function of the body, this provision to be for purposes of the act and not to regulate legalized practice of the healing art

10 To prohibit the addition of drugs to foods and confections intended or offered for general human consumption, but not to prohibit such addition to, or other modification of, foods and confections intended or offered to meet special nutritional requirements or dietary needs, provided the label and advertising of products so treated plainly declare the character and purpose of such modifications

11 To require that testimonials and opinions used in advertising of drugs and drug preparations be accompanied by the name and address of the writers thereof, and to consider such testimonials and opinions as advertising claims of the advertiser

12 To provide by permit or license or other means for government control over the sale and distribution of such drugs and therapeutic agents as cannot be adequately controlled by gross inspection or chemical examination of the finished product, except that this shall not apply to the provisions of the Serums and Vaccines Act of 1902 and amendment thereto

13 To require each importer, manufacturer, jobber and retailer engaged in interstate commerce in drugs and therapeutic agents to register with the government his name, place of business, and the character of the business in which he is engaged or proposes to engage, such registration to be granted without cost to the applicant and accepted only on evidence showing adequacy of plant, equipment and personnel for the business proposed

14 To provide for cooperation between federal and state governments in the enforcement of food and drug laws in their respective jurisdictions on a plan similar to that provided in 'An Act to Create in the Treasury Department a Bureau of Narcotics, and for Other Purposes' approved June 14, 1930

15 To require labels on drugs and drug preparations to bear the name and address of the manufacturer, seller or distributor, and to bear a statement of the net weight or volume of contents

16 To provide for more adequate penalties, which will be commensurate with the seriousness of violations

Report of the Committee on Foods on Revision of the Food and Drugs Act with Special Reference to Foods

The Committee on Foods of the American Medical Association, solely from the standpoint of greater consumer protection with respect to nutrition and health deems it desirable that the present Food and Drugs Act be amended (or a new law made)

1 To include provisions for so regulating all forms of food advertising that it shall be truthful in statement and by implication.

2 To ban the use of names of diseases on the labels and in lay advertising of common foods but not to exclude names of nutritional disorders arising from inadequacy of the diet in nutritional essentials or of disease names from the labels and advertising for special purpose foods which are useful in the diet during the course of such diseases

3 To ban the use of testimonials of a health, medicinal or therapeutic character, or with such implication in food advertising by persons unqualified to express a scientific authoritative opinion or judgment on the subject of the testimonials

4 To authorize the fixing of tolerances for any added or natural poison in or on food and consider food as adulterated which *bears or contains* any poisonous or deleterious substance, in excess of the tolerances, which may render it dangerous to health irrespective of whether that constituent is *added by man or exists there naturally*

5 To prevent the use of non-food material such as resinous glaze or shellac to cover confectionery

6 To ban the embedding of metallic trinkets in confectionery, which may result in their aspiration and lodgment in the windpipe

7 To prohibit the use of any artificial colors in food other than those certified by the Department of Agriculture, thereby preventing the use of toxic colors

8 To class as adulterated food prepared under insanitary conditions whereby it may have become contaminated with filth

9 To include a provision against packing food in containers or wrappings which may injuriously contaminate the food

10 To authorize the establishment of legal definitions and standards for foods

11 To consider as adulterated a food purporting to be one for which a definition and standard has been prescribed if it fails to conform to such definition and standard, and the label does not conspicuously indicate deviations from the definition and standard

12 To require that the label of foods shall bear their common or usual names if there are any, and in conjunction with the names declare the common or usual name of each ingredient article used in the manufacture of the food in the order of decreasing predominance by weight, exceptions being made for spices or other condiments, colors, flavors and leavening agents

13 To require that fanciful trade names for food be accompanied by statements identifying the ingredient articles used in the manufacture of the food in the order of decreasing predominance by weight, exceptions being made for spices or other condiments, colors, flavors and leavening agents

14 To require that informative statements required on labels be conspicuously placed thereon in simple common terms so as to be readily observed at the time and under the conditions of purchase.

15 To require that the labels of Special Purpose Foods with usefulness restricted to specific purposes such as inclusion in diets for obesity or special morbid conditions, shall prominently display in bold type the designation 'Special Purpose Food' a statement listing all ingredients in the order of decreasing predominance by weight, and the special purpose of the product. These statements, so far as is practical, should be in close proximity to the trade name. In addition, as much of the following information should be given as is significant to permit the intelligent use of the particular product by the consumer: specific properties, vitamin and mineral content, the calories per gram or ounce, and the grams each of carbohydrate protein and fat per portion

16 To require that special values or properties of food, if given, be stated in specific recognized technical terms or units

17 To require that labels bear the name and place of business of the manufacturer, seller or distributor of foods

18 To authorize federal enforcement officials to enter on and inspect premises of those manufacturing, storing and dealing in foods in order to protect adequately the health of the public.

19 To authorize certain officials to effect seizure of food before the filing of a libel in court, and to hold same pending court action where the evidence before the enforcement officials is such as to indicate that the food is imminently dangerous to health

20 To provide adequate penalties for those violations of the law affecting the nutrition and health of the consumer

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45 central standard time. The next three broadcasts will be as follows

January 17	The Good Old Days	W W Bauer	M D
January 24	Progress Against Arthritis	Irving S. Cutler	M D
January 31	Thirty Six Thousand Deaths	W W Bauer	M D

National Broadcasting Company

The American Medical Association broadcasts under the title 'Your Health' on the Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4 15, central standard time. The next three broadcasts will be as follows

January 15	Causes of Death in 1933	W W Bauer	M D
January 22	Health in Winter	W W Bauer	M D
January 29	Organizing for Health	Morris Fishbein	M D

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Society News—The Tuscaloosa County Medical Society was addressed, December 14, by Dr James S. McLester Birmingham, on 'Old Age A Philosophy for the Later Years'. Speakers before the November meeting of the society were Drs Chalmers H. Moore, Birmingham, on 'The Scope of Neurosurgery' and John H. Ferguson, University, 'The Autonomic Control of Gastric Function'. The annual homecoming meeting of the Talladega County Medical Society was addressed, December 11, by Drs H. Earle Conwell Birmingham on 'Fracture Problems' and Frederick W. Wilkerson, Montgomery, 'Nervous Indigestion'. Dr Wilmot S. Littlejohn, Birmingham, addressed the Walker County Medical Society, November 9, on 'Pituitary Tumors'.

DISTRICT OF COLUMBIA

District Society Meetings—The meeting of the Medical Society of the District of Columbia, January 9, was a joint one with the Washington Urological Society, speakers were Drs Charles C. Higgins, Cleveland, and Linwood D. Keyser, Roanoke, Va., on 'Experimental and Practical Clinical Observations on Urinary Lithiasis'. The society will be addressed, January 16, by Drs Charles A. Schutz, on 'Evaporated Milk and the Child Welfare Infant', Harry F. Dowling, 'Rapid Diagnosis and Serum Treatment of Lobar Pneumonia' and William Cabell Moore, 'Industrial Medicine and Medical Ethics'. January 23 the program will be presented by Drs George L. Weller, Jr., on 'Early Clinical Recognition of Adrenal Insufficiency Resulting from Partial or Total Atrophy of the Adrenal Glands', James Alexander Lyon and Edmund Horgan, 'A Further Report on the Dissociation of the Thyroid from the Sympathetic Nervous System and Reduction of the Blood Supply to the Thyroid in the Treatment of Angina Pectoris', and Harry S. Bernton, 'Hygiene of Hay Fever'.

FLORIDA

Personal—The Edward C. DeSaussure Post number 9, American Legion department of Florida recently presented its medal for outstanding and distinguished service to the community during 1934 to Dr Frank L. Fort, Jacksonville. Dr Fort has served the crippled children of the state for ten years, first for the state board of health and more recently for the Florida Crippled Children's Commission.

Society News—A recent meeting of the Florida Midland Medical Society was addressed at Bartow, among others by Drs James L. Estes, Tampa, on 'Surgical Accidents Occurring in the Urinary Tract Following Operation', and Jack Halton, Tampa, 'Anal Pruritus—Significance of Cryptitis Papillitis and Other Rectal Pathology'. Dr Arthur R. Knauf, Tampa, discussed treatment of the enlarged prostate before the De Soto-

Hardee-Highlands Counties Medical Society recently—The Lake County Medical Society was recently addressed in Tavares by Dr. Lonnie W. Grove, Atlanta, on "Surgical Aspects of the Gallbladder and Results of Eighty-Four Operations"—At a meeting of the Pasco Hernando-Citrus County Medical Society, November 8, in Dade City, Dr. Shuler H. Etheredge, Tampa, spoke on "General Edema and Chronic Nephritis."

GEORGIA

Supervisor for Emergency Relief Appointed—Dr. Marvin F. Haygood, superintendent of the tuberculosis sanatorium at Alto, has been granted an indefinite leave of absence to become medical supervisor for the federal emergency relief administration in Georgia.

New Buildings at Georgia Warm Springs—Dr. LeRoy W. Hubbard, director of extension, Georgia Warm Springs Foundation, states that the buildings erected recently at the foundation were not financed by funds subscribed at charity balls in honor of the President's birthday. They were erected by contributions of material and money obtained from many sources by Messrs. Hegeman and Harris, New York builders, who gave their services and those of their staff. They presented the buildings to the foundation through the President on Thanksgiving Day. The news item in *THE JOURNAL*, December 22, page 1954, was based on a report in the *New York Times*, November 28. According to Dr. Hubbard, a portion of the money raised through the birthday balls in 1934 was set aside to be drawn on for buildings as the need developed, but this fund is still intact.

ILLINOIS

Influenza in Veterans' Hospital—It is reported that quarantine was ordered at the Veterans' Administration Facility in Hines, December 29, following an outbreak of influenza. One hundred patients were said to be ill with the disease.

A Year Without Ophthalmia Neonatorum—For the first time in the history of Illinois, no cases of ophthalmia neonatorum were reported during the year ended July 1, 1934, according to the *Chicago Tribune*. The enactment of the law in 1933 providing for the use of silver nitrate solution in an infant's eyes immediately following its birth is credited with this result.

Chicago

Hospital Editor Dies—Matthew O. Foley, for fifteen years managing editor of *Hospital Management*, a monthly journal, died at his home, January 4, of heart disease. Mr. Foley was 45 years old.

Physician Sentenced—Dr. Lou E. Davis was sentenced to four years in the women's prison at Dwight Ill., December 6, by Judge Grover C. Niemeyer in the criminal court. Dr. Davis was found guilty November 27, on a charge of having performed an illegal operation.

University News—The Beaumont Foundation, Cleveland, has made a grant to the University of Chicago for the support of research by Dr. Julius M. Rogoff on the suprarenal and other endocrine glands. Dr. Rogoff was formerly associate professor of experimental medicine at Western Reserve University School of Medicine, Cleveland.

Dr. Fraenkel Gives Bacon Lectures—Dr. Ludwig Fraenkel, professor and head of the department of gynecology and obstetrics, University of Breslau, Germany, will deliver the fifth series of Charles Sumner Bacon Lectures, sponsored by the University of Illinois College of Medicine. The titles of the lectures and the dates are:

Recent Advances in Gynecologic Endocrinology, January 16
 Practical Application of the New Knowledge of Hormones, January 17
 Origin, Migration and Elimination of Uterine Myomas, January 18

Program on Cerebral Infections—A symposium on cerebral infections will be presented before the Chicago Medical Society, January 16, by members of the faculty of Loyola University School of Medicine. Dr. Francis J. Gerty, professor and director of the division of neurology and psychiatry, will discuss the diagnosis. Dr. Victor E. Gonda, clinical professor in the division of medical management, and Dr. Harold C. Voris, associate clinical professor of surgery, surgical management. Overweight was the theme of a lay educational program sponsored by the society, January 9. Speakers were Drs. Samuel Soskin, director of metabolic research, Michael Reese Hospital, on "A Common Sense View of Overweight" and George A. Harrop, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, "Treatment of Overweight." A dinner preceded the meeting.

Society News—Speakers before the Chicago Surgical Society, January 4, included Drs. Ralph A. Kordenat on "The Relation of Anemia to Surgical Disease of the Gallbladder," and Charles F. Sawyer, "Factors Influencing Mortality in Appendicitis."—At a meeting of the Chicago Council of Medical Women, January 4, Helen Koch, Ph.D., associate professor of child psychology, department of home economics, University of Chicago, spoke on "The Nursery School and the Mental and Physical Health of Young Children" and Ethel Kavin, psychologist of the laboratory schools of the University of Chicago, "Psychologic Problems Arising from Physical Illnesses in Children."—Dr. Irving I. Muskat discussed

"Tuberculosis of the Middle Ear in Pulmonary Tuberculosis," among other speakers, before the Chicago Laryngological and Otological Society, January 7.—A joint meeting of the Chicago Orthopedic Society and the Chicago Roentgen Society was addressed, January 10, by Drs. Edward L. Jenkinson on "Bone Lesions" and Dallas B. Phemister on "Pathology and Diagnosis of Tuberculous Arthritis."—Dr. Otto Saphir, among others, will address the Chicago Pathological Society, January 14, on "Anomalies of the Circle of Willis and Resulting Vascular Disturbances of the Brain."—Speakers before the Chicago Club for the Study of Arthritis, January 9, were Drs. Isadore Pilot on "Pathology of Gout" and Edwin P. Jordan, "Clinical Aspects and Relation to Chronic Arthritis." Dr. Emil G. Vrtak gave a demonstration of slides and patients.

INDIANA

Anonymous Gift for Nutrition Camp—The Marion County Tuberculosis Association has been given an anonymous donation of \$50,000 to aid in the enlargement and maintenance of its Nutrition Camp for Sick Children near Bridgeport. The association established the camp in 1928 with accommodations for thirty children, but since that time expansion has been retarded because of insufficient funds. The camp is considered a training school for development of health habits in children. When children return to their homes, nurses of the association remain in constant touch with their families to help revise the child's health program.

Secretaries' Conference—The annual secretaries' conference of the Indiana State Medical Association will be held at the Indianapolis Athletic Club, Indianapolis, January 27. Speakers will include the following:

William J. Burns, executive secretary, Wayne County Medical Society
 Detroit on the society's demonstration
 Dr. Claude B. Paynter, Salem, Care of the Indigent Sick
 Dr. Elias H. Brubaker, Flora, Programs for the Average Sized Medical Society
 Dr. Orville M. Graves, Princeton, Relationship of the Medical Society to Social Workers and Nurses
 Dr. Joseph L. Allen, Greenfield, Cooperation of Doctors and Dentists in County Society Organization Work
 Dr. Walter L. Biering, Des Moines, Iowa, President, American Medical Association, Work of the Medical Advisory Group of the President's Committee on Economic Security
 Dr. Willis D. Gatch, dean, Indiana University School of Medicine, Indianapolis, Comments on Indiana Division of Public Health Set L.P.
 Albert G. Milbank, chairman, board of directors, Milbank Memorial Fund, New York, Relationship of the Milbank Memorial Fund to the Field of Health and the Medical Profession
 Dr. Samuel T. Miller, Elkhart, Public Health Educational Work by the Medical Society
 Dr. Oliver J. Fay, chairman, board of trustees, Iowa State Medical Society, Essentials of Medical Progress
 Dr. Eldridge M. Shanklin, Hammond, editor of the *Journal of the Indiana State Medical Association*, The Journal and the County Medical Society

KENTUCKY

Society News—Dr. Eric M. Matsner, New York, will address the Jefferson County Medical Society, Louisville, January 21, on "Medical Aspects of Birth Control."—Dr. Harvey J. Howard, St. Louis, addressed the Louisville Eye and Ear Society, January 10, on "Practice of Modern Medicine in the Field of Ophthalmology."—Dr. William O. Johnson will present a paper on "The Thyroid in Pregnancy" at a meeting of the Louisville Obstetrical and Gynecological Society, January 28.

MARYLAND

Dr. Ledingham Gives Herter Lectures—Dr. John Charles Grant Ledingham, director, Lister Institute, London, England, delivered the twenty-second course of lectures under the Herter Foundation, December 5-7, at Johns Hopkins University School of Medicine, Baltimore. Under the general title "Studies on Virus Problems" Dr. Ledingham's lectures were "Tissue and Cell Affinities of Viruses and Reactions of the Host," "Cultivation Methods, The Development of Antibodies, in Particular, the Antiviral Body" and "The Elementary Bodies in Virus Infections and the Filterable Avian Tumors and Their Etiological Significance. The Outlook for the Future."

De Lamar Lectures—The next lecture in the series of De Lamar Lectures at Johns Hopkins University School of Medicine, Baltimore, will be given, January 15, by Dr Leslie T Webster of the Rockefeller Institute for Medical Research. His subject will be "Host Response to Infectious Agents." Other speakers will be

Harrison P Eddy S B civil engineer Boston February 19 Municipal Sanitation and the Public Health

Dr Frederic Maurice McPhedran of the Henry Phipps Institute University of Pennsylvania Philadelphia March 19 The Pathogenesis of Tuberculosis in Relation to Its Public Health Economics

Richard E Scammon Ph D dean of medical sciences University of Minnesota Minneapolis early in April The Effect of Plague on Western Europe

The series opened, November 20, when Dr James Angus Doull, professor of hygiene and public health, Western Reserve University School of Medicine discussed "The Epidemiology of Leprosy with Particular Reference to a Recent Study in the Philippines." Alfred J Lotka, D Sc, general supervisor, statistical bureau, Metropolitan Life Insurance Company, spoke, December 4, on "The Adventure of Life."

MASSACHUSETTS

Bill Introduced—S 52 proposes to accord liens to physicians and hospitals treating or caring for persons injured through the negligence of another, on all rights of action claims, settlements, compromises or judgments accruing to the injured persons by reason of their injuries

Personal—Dr John Francis Curtin North Abington, has been named medical examiner of the second Plymouth district and Dr William J Pelletier, Turners Falls, associate medical examiner, eastern Franklin district.—Dr Conrad Wesselhoeft, Boston, was recently awarded the oak-leaf cluster for the Distinguished Service Cross, "for extraordinary heroism in action during the Aisne-Marne Offensive, France, July 18-26, 1918"

Psychiatric Internships—The Worcester State Hospital announces six psychiatric internships of twelve months to begin July 1. Registration must be made before March 1 and the examination will be held March 15 at the hospital. In addition to a rotating service in medical and surgical wards, organized instruction in the following courses will be offered: clinical psychiatry, psychoanalysis, administrative psychiatry, biopsychiatry, juvenile psychiatry, psychiatric social service, neuropathology, fever therapy, endocrines in psychiatry, research methodology, psychometrics in psychiatry and biometrics. The hospital provides maintenance. Unmarried graduates of class A medical schools who have completed an accredited internship in medicine are eligible. Applications should be addressed to the director of clinical psychiatry at Worcester State Hospital, Worcester, Mass.

Society News—At a meeting of the Massachusetts Psychiatric Society, December 14 a symposium on experimental studies of the heart rate was presented by Drs Moses Ralph Kaufman, Cambridge, Jackson M Thomas and John C Whitehorn, both of Belmont.—Speakers before the Worcester District Medical Society, December 12, included Drs Andrew E. O Connell on "Excretory Urography" and William E Murphy "Cancer of the Larynx."—Dr Donald S King, Boston addressed the New England Roentgen Ray Society, December 21, on "The Lateral X-Ray Film in the Diagnosis of Pathology in the Region of the Middle Lobe."—Mr James F Ballard, director of the Boston Medical Library, discussed medieval and Renaissance textual manuscripts and early printed books before 1600 A. D. before the Boston Medical History Club December 17.—The Brookfield Medical Club was addressed December 19, by Dr Samuel H Epstein, Boston, on "Treatment of General Paresis with Tryparsamide."—Dr Frank R. Ober, Boston, addressed the New England Physical Therapy Society, December 19, on "Relation of Muscle Atrophy to Joint Injury and the Value of Physical Therapy in This Condition."—Among others, Dr Henry M Emmons, Boston spoke before the New England Ophthalmological Society, December 18, on "Development of the Organ of Vision from Its Lowest Form Up to the Eye of the Primates"

NEW YORK

Eight Years Under the Medical Practice Act—During the period from 1926 when the present medical practice act went into effect, to July 1934, the state education department investigated 3395 complaints of illegal practice, according to Dr Harold Rypins secretary of the state board of medical examiners. In 1345 cases it was shown that there was no cause for action and in 1,488 cases the violations were stopped without prosecution. Among the 562 prosecutions 473 con-

victions were obtained, 84 per cent. Thirty-six cases resulted in acquittals, forty-one were withdrawn and twelve are pending trial. In the past six years the Medical Grievance Committee has considered 397 complaints against licensed physicians. Of this number 355 were disposed of by the committee, twenty-six were referred to the board of regents. Of the latter, the board revoked eleven licenses and suspended six. Formal censure was ordered in eight cases and one was dismissed. Sixteen are pending.

New York City

Appointments at New York University—The Council of New York University and Bellevue Hospital Medical College has recently announced the following appointments:

Dr Sigmund A Agatston assistant clinical professor of ophthalmology
Dr James Burns Amberson Jr assistant professor of clinical medicine
Dr Carter N Colbert clinical professor of psychiatry
Dr Edward B Gresser assistant professor of ophthalmology
Dr James Swift Hanley assistant clinical professor of otorhinolaryngology
Dr Emery A Rovenstine assistant professor of surgery

Harvey Lectures—The fourth Harvey Lecture of the year will be given by Alfred N Richards, Ph D, professor of pharmacology, University of Pennsylvania School of Medicine Philadelphia, January 17, at the New York Academy of Medicine, on "Processes of Urine Formation in the Amphibian Kidney." The fifth lecture will be delivered by Dr Edward C Dodds director of the Courtauld Institute of Biochemistry the Middlesex Hospital, London, February 2, on "Specificity in Relation to Hormone and Other Biologic Reactions"

Society News—Dr Allan Roy Dafee, Callander, Ont. delivered a public lecture on the Dionne quintuplets at Carnegie Hall, December 10.—Speakers at a meeting of the New York Neurological Society with the section on neurology and psychiatry of the New York Academy of Medicine, January 8, were Drs Ade T Milhorat and Harold G Wolff, on "Creatine Metabolism in Muscle Disease", Carlyle F Jacobsen, Ph D, New Haven, Conn, "Experimental Analysis of the Functions of the Frontal Association Areas in Primates," and Dr Gregory Zilboorg, "Sidelights in the Psychology of Murder."—The eighth afternoon lecture of the New York Academy of Medicine was given January 4, by Dr Israel Strauss on "Recognition of Early Symptoms of Brain Tumors." The ninth was presented by Dr Josephine B Neal, January 11, on "Diagnosis and Treatment of Meningitis" and the tenth will be by Dr James Ewing, January 18, on "Relationship of Trauma to Malignancy."—Drs Francis C Grant, Philadelphia, and Eli Jefferson Browder, Brooklyn, addressed the Medical Society of the County of Kings, December 18, on "Surgical Relief of Pain and 'The Syndrome of the So-Called Pulmonary Sulcus Tumors,' respectively.—Dr Joseph C. Doane, Philadelphia addressed the National Society for the Advancement of Gastro-Enterology, December 26, on "The Effect of Feeding of Acid and Base Foods on the Reaction of Bodily Secretions and Excretions"—Drs Morris Fishbein, Chicago, editor of THE JOURNAL, and Willard C Rappleye dean of Columbia University College of Physicians and Surgeons, addressed the Harlem Medical Association, January 2, on "Economic Security and Medical Care" and "Recent Trends in Medical Education, respectively"

New Records in Health—Despite the unfavorable influences of the economic depression, New York City established several new records in health during 1934. The general death rate was 10.15 per thousand of population, the lowest in the history of the city, the actual number of deaths was 75,857. The greatest number of deaths (30,948) occurred in the group of diseases of the heart, arteries and kidneys, including cerebral hemorrhage. Tuberculosis which has steadily decreased in the last ten years, caused 3,950 deaths, a rate of 52.85 per hundred thousand. This result, a new low point, was attributed to efficient organization of relief and to intensified control activities, such as improved x-ray equipment, extension of facilities for pneumothorax treatment and better follow up of cases. The pneumonia death rate in 1934 was the lowest on record, but this was partly attributed to the low prevalence of measles and the absence of an influenza epidemic. Fewer cases of diphtheria were reported to the health department than in 1933, but deaths increased from 86 to 103, indicating a more severe type of the disease according to the report. The death rate from whooping cough declined from 25.7 in 1933 to 21.99 per hundred thousand of population under 5 years of age in 1934. Only 76 cases of poliomyelitis were reported with 12 deaths. There were 44 deaths from typhoid, a rate of 0.59 per hundred thousand of population new low records. The cancer death rate has again increased being 127.1 as compared with 121.6 in 1933. The health department has endeavored to

focus attention on diabetes as a health problem but, as it is not a reportable disease, figures on its prevalence are not available. The registered death rate rose in 1934 to 30.3 from 29.1 in 1933, but this is believed to be due to the aging of the city's population and to more frequent recognition of the disease. Appendicitis mortality was lower than at any time in the last five years, 13.45 as compared with 15.64 in 1934 and 16.32 in 1931. The death rate from automobile accidents declined from 15.45 in 1933 to 15.28 in 1934; the rate in 1930 was 18.53. The suicide death rate, which began to increase in 1929, reached its highest point (22.1) in 1932 and in 1934 decreased to 16.43. The infant mortality rate in 1934 was 52.22 per thousand births, a reduction from 1933 but not so low as the 1932 rate, 50.91. The birth rate continued to drop, being 13.55 per thousand of population in comparison with 17.64 in 1930. During the past year the department has designated certain "sore spots" on which it is concentrating its activity in an effort to improve health conditions that are vastly worse than those in the city as a whole. These areas are Central Harlem, the lower West Side, Red Hook-Gowanus and Williamsburg-Greenvpoint.

OKLAHOMA

Society News—Drs William C. Burgess, Ringling and Lisby L. Wade, Ryan, addressed the Jefferson County Medical Society, Waurika, November 5, on rheumatic fever and urinalysis, respectively. Among speakers at a meeting of the Southeastern Oklahoma Medical Association at McAlester, December 6, were Drs Daniel E. Little, Eufaula, on "Intravenous Administration of Hydrochloric Acid"; John H. Veazey, Madill, "Typhoid Fever in Children"; and Leonard S. Willour, McAlester, "Skeletal Traction in Fractures of the Thigh and Leg." At a meeting of the Southern Oklahoma Medical Association, Ardmore, December 4, speakers included Drs Alfred I. Folsom, Dallas, on transurethral prostatectomy; Darrell G. Duncan, Oklahoma City, dermatologic manifestations of syphilis; and James Floyd Moorman, Oklahoma City, tuberculosis. Drs Coble D. Strother, Sherman, Texas, and Raymond L. Murdoch, Oklahoma City, addressed the Bryan County Medical Society, Durant, November 12, on "Useful Drugs in the Treatment of Heart Disease" and "Common Anorectal Diseases," respectively. Drs Hugh G. Jeter and Lewis J. Moorman, Oklahoma City, were speakers before the Okfuskee-Okmulgee County Medical Societies, Okemah, November 19, on anemia and diseases of the chest, respectively.

PENNSYLVANIA

Physician Appointed State Secretary of Welfare—Dr James Evans Scheehle, Llanerch, has been appointed secretary of welfare in the cabinet of the incoming governor. Dr Scheehle, who was graduated from the Medico-Chirurgical College of Philadelphia in 1906, has recently been coroner of Delaware County.

Society News—Drs Holbert J. Nixon, Uniontown and Chester B. Johnson, Allison, addressed the Fayette County Medical Society, Uniontown, January 3, on "Hyperchromic and Hypochromic Anemias of Pregnancy" and "Ergot in Pneumonia," respectively. Dr Floyd E. Keene, Philadelphia, addressed the Harrisburg Academy of Medicine, December 18, on "Present Status of Glandular Secretions and Therapy." The Pennsylvania Tuberculosis Society will hold its annual meeting in Pittsburgh, February 19-20, in conjunction with the annual session of the Pennsylvania Conference for Social Welfare.

Philadelphia

Seminars on Nutrition—The January series of postgraduate seminars sponsored by the Philadelphia County Medical Society includes the following program:

- January 4 Dr Jacob Earl Thomas, The Physiology of Digestion
- January 11 Elmer V. McCollum, Ph.D., Baltimore, The Vitamins
- January 18 Dr Rufus S. Reeves, Important Scientific Factors in the Production of the Balanced Diet
- January 25 Dr Maurice B. Strauss, Boston, The Role of Faulty Assimilation in the Production of Anemia Including Postoperative and Malignant Lesions as Possible Factors

Patents on Medical Discoveries Prohibited—The University of Pennsylvania recently announced the adoption of a policy prohibiting the patenting for profit by any one connected with it of any invention or discovery affecting the public health. Neither the university nor any one in its employ will be permitted to patent new drugs, processes or apparatus invented or discovered that are intended for medical or surgical use. It has never been the practice of the university to patent such discoveries, but there has never before been a definite ruling against it.

Pittsburgh

Personal—Roswell H. Johnson, M.S., formerly of the University of Pittsburgh has been appointed social hygienist in the Palmyra Settlement, Honolulu, and part time professor in the University of Hawaii. He will give courses in social hygiene and eugenics.

Course in Public Speaking for Physicians—The Allegheny County Medical Society is offering to its members a course in public speaking conducted by Wayland M. Parrish, Ph.D., professor of English at the University of Pittsburgh. Brief lectures are presented by the instructor on the principles of persuasive speaking, selection and organization of materials, their psychologic adaptations to audiences and their delivery. Members of the class make brief talks, with criticisms and suggestions by Professor Parrish. Sessions are held at the Pittsburgh Academy of Medicine, Tuesday and Friday afternoons. They began January 4 and will continue for ten sessions.

SOUTH CAROLINA

Graduate Courses in Obstetrics—The South Carolina Medical Association announces a series of courses in obstetrics for physicians of the state to be given during the coming year beginning in April, with Dr James R. McCord, Atlanta, as the instructor. Each course will begin on Monday and run through Friday. The following dates and places have been chosen: Anderson, April 15; Spartanburg, June 24; Columbia, July 8; Orangeburg, July 22; Florence, August 12; Kingstree, August 26; and Charleston, September 9. The course is part of a campaign to reduce maternal mortality in the state, according to the *Journal of the South Carolina Medical Association*.

Society News—Drs Alfred R. Shands Jr. and Fred M. Hanes, Durham, N.C., among others, addressed the Pee Dee Medical Association at its annual meeting in Florence, December 5, on arthritis and therapeutics, respectively. Speakers at a meeting of the Fifth District Medical Society in Chester, November 20, included Drs Robert Wilson, Charleston, on "Hypertensive Heart Disease"; Henry L. Sloan, Charlotte, N.C., "Recent Advances in Ophthalmology"; and William Weston, Columbia, "Rheumatic Fever in Children." Dr Hugh P. Smith, Greenville, presented a motion picture on electrocardiography at a meeting of the Greenwood County Medical Society, Greenwood, in December.

VIRGINIA

Special Course at University—The department of medicine of the University of Virginia in cooperation with the Virginia Society of Otolaryngology and Ophthalmology held a special course in those subjects December 5-8. Those who assisted in conducting the course were Drs John M. Wheeler, Conrad Berens, John H. Dunnington, Ebenezer Ross, Faulkner, John R. Page and Mr Edgar B. Burchell, all of New York, and Dr George M. Coates, Philadelphia. Of the university staff the following gave lectures or conducted clinics: Drs Fletcher D. Woodward, Vincent W. Archer, Oscar Swineford Jr., Halstead S. Hedges and Edwin W. Burton.

Society News—At a meeting of the Postgraduate Medical Society of Southern Virginia in Clarksville, November 20, speakers included Drs John Shelton Horsley, Richmond, on "Cancer of the Stomach"; James Edwin Wood Jr., University, "Treatment of Congestive Heart Failure (Old Methods and New Modifications);" and J. Bolling Jones, Petersburg, "Importance of Early X-Ray Studies of the Urinary Tract in Pyelitis of Pregnancy." Drs Lemuel R. Broome, Catawba Sanatorium, and John E. Gardner, Roanoke, addressed the Roanoke Academy of Medicine, November 5, on "Collapse Therapy of Tuberculosis" and "Thrombosis of the Left Auricle," respectively.

WASHINGTON

Society News—Dr Vernal G. Bachman, Pasco, presented a paper on medical economics before the Klickitat-Skamania Counties Medical Society recently, among other speakers, Dr William R. Frazier, Portland, Ore., discussed "Modern Technic in Home Delivery." Dr Winfred H. Bueermann, Portland, Ore., addressed the Lewis County Medical Society, Chehalis, November 12, on cancer. Drs Thomas M. Joyce and Noble W. Jones, Portland, addressed the Cowlitz County Medical Society, Longview, November 13, on "Cancer of the Breast and Various Complications of the Disease" and "Diseases of the Heart," respectively. Drs James Howard Manning and Julius A. Weber, Seattle, presented papers before the Walla Walla Valley Medical Society, Walla Walla,

November 8, on "Recent Developments in Treating Diseases of the Rectum" and "Use of the Bronchoscope in Diagnosis and Management of Lung Conditions," respectively—Speakers at a meeting of the Yakima County Medical Society, Yakima, November 12, were Drs Milton B Steiner and Leo S Lucas, Portland, on "Eye Injuries and 'Early and Late Treatment of Poliomyelitis, respectively—Dr Charles E Sears Portland, Ore presented an address on jaundice at a meeting of the Spokane County Medical Society Spokane, November 8 and Dr Joseph E Bittner Jr Yakima demonstrated a device for treating fractures of the forearm and leg—Dr Bernard Myers, London addressed a special meeting of the Seattle Pediatric Society, December 1 on infant feeding

GENERAL

License Stolen—Dr Woodie Dozier McCune Chicago reports that his license to practice medicine in Illinois was taken from his office about December 21 The license, number 14910, was issued Aug 22, 1922

Urologic Congress—Members of the faculties of medical schools and of special societies in the United States are invited to attend a congress on urology under the sponsorship of the Brazilian Society of Urology in Rio de Janeiro January 21-26 Official subjects of discussion will be problems of tropical urology endoscopic surgery of the prostate social importance of infections of the masculine genitalia and renal insufficiency in urinary surgery The invitation was offered through the Brazilian ambassador to the United States

Physicians Elected to Legislative Bodies—*Northwest Medicine* reports that several physicians were sent to the legislatures of the three states it represents In Oregon Drs James A Best, Pendleton Clyde T Hockett, Enterprise and Jacob F Hosch Bend were elected In Washington Dr Dale O Nugent, Centralia, is a holdover member of the senate and Drs Robert D Wiswall Vancouver Delmar F Bice Yakima and Ulric S Ford Forks were elected In Idaho three were reelected Drs Owen T Stratton Salmon Dailey C Ray Pocatello, and Mary A Callaway Boise

Interim Revision of Pharmacopeia—E Fullerton Cook Ph M, Philadelphia, chairman of the U S Pharmacopeia Committee of Revision announces the third interim revision which will become official and enforceable May 1 The announcement primarily covers modifications in the assay for ergot and the fluid extract of ergot replacing interim revision No 1 issued Jan 1, 1934 Since that time it has been found desirable to adopt the alkaloidal salt ergotoxine ethanesulfonate as the official ergot standard For the purpose of assuring uniformity the U S P board of trustees has arranged for the packaging in ampules, under nitrogen of a standardized lot of the salt which may be obtained from the chairman, Forty-Third Street and Woodland Avenue Philadelphia Any one who wishes a copy of the revision announcement may obtain it from the same address by sending 10 cents to cover the cost of printing and distribution

Society News—Dr Reginald H Jackson Madison Wis was elected president of the Western Surgical Association at its annual meeting in St Louis December 7-8 Dr Fred W Bailey, St Louis, was elected vice president, and Dr Albert H. Montgomery Chicago secretary The 1935 meeting will be held in Rochester, Minn—Dr Stanhope Bayne-Jones, New Haven, Conn, was elected vice president for the section on medical sciences of the American Association for the Advancement of Science at its midwinter meeting in Pittsburgh December 27-January 2 Karl T Compton Ph D, president of Massachusetts Institute of Technology Cambridge was chosen president of the association—Dr Maurice W Samuels, Chicago has been reelected president of the Hotel Physicians Association of America Other officers are Drs Lee H Kiel Chicago secretary Joseph D Nagel New York Frank L Willman Washington, D C William T Harsha Chicago, Daniel T Mahoney Boston vice presidents—At the meeting of the Society of American Bacteriologists December 27-29 in Chicago Karl F Meyer Ph D, Hooper Foundation for Medical Research, San Francisco was elected president Dr Thomas M Rivers of the Rockefeller Institute for Medical Research New York vice president, and Ira L Baldwin Ph D of the University of Wisconsin secretary The next annual meeting will be held in New York—The American Birth Control League will hold its annual meeting in Chicago January 16-17 at the Palmer House An evening conference of physicians will be held Tuesday with Dr Fred L Adair Chicago as the presiding officer Speakers will be Drs Alexander M Campbell Grand Rapids, Mich Charles Sumner Bacon Irving F Stein and Rachelle S Yarros Chicago and Eric M Matsner New York.

Osteopaths Again Attempt to Obtain Recognition

The failure of the attempts of osteopaths to obtain registration and therefore state recognition has been reported in previous letters Their latest attempt has thus far been more successful In the house of lords, Viscount Elibank moved the second reading of the bill for the registration and regulation of osteopaths The mover said that osteopathy was a system of healing which largely dispensed with the use of drugs Osteopaths claimed to treat disease on the principle that most diseases had their origin in some maladjustment of the body framework The osteopath did not believe that drugs effected a cure but that the body itself, when it functioned properly would effect its own remedy for disease He said that the laws regulating medical practice should not allow any unreasonable obstacle to lie in the way of the development of this school of thought Osteopaths did not ask to be admitted to the medical profession, they asked to be admitted to an osteopaths' register and that only qualified osteopaths should be registered The purpose of the bill he said was to prevent the practice of osteopathy by those who were not qualified

Lord Mounihan moved the rejection of the bill He said that it involved negation of all the principles embodied in the medical act of 1858 That act enabled every one to discriminate between those who had and those who had not passed through the medical curriculum between the qualified and the unqualified practitioner The act was inspired by a desire to protect the public against dangerous people who had undergone no medical training in those fundamental sciences on which medicine was based The bill would set aside all the defenses erected for the protection of the public If one particular theory of medicine was guaranteed recognition, it would not be long before other cults would make appeals for it Acceptance of the bill would hold up to obloquy the whole of the scientific basis of medicine today Osteopathy had no connection with the main stem of scientific medicine Medicine and osteopathy did not run on parallel lines They were not complementary to each other but in direct opposition This bill would create two standards of entry into the medical profession If osteopaths were at last recognizing that a formal medical training was necessary, there was nothing to prevent them from passing through the medical curriculum The bill was an endeavor to destroy the unity of medicine and to force on the public which was unaware of the danger a spurious science that set aside the accumulated wisdom and the expert practice of centuries

Lord Dawson president of the Royal College of Physicians said that the bill raised an important question of principle Certain callings by long custom or statute had a prescribed course of training laid down Examples were the law, the master mariner and medicine Supposing a body of persons said that they wanted to train persons for the law or as captains in Atlantic liners and would do it in their own way, without reference to the existing system their request would receive an emphatic negative Why should there be any difference in the case of medicine which had a grave responsibility for human life? There was complete liberty of thought in the medical profession Many physicians who had been trained for the medical profession practiced osteopathy The profession said that the osteopaths must go through the medical training and then they would be free to do what they liked There must be a preliminary nonvocational training to make the trained

mind. Only when the medical schools were satisfied with the basic training of the students were they permitted to enter on the vocational part of their training. For five years the medical student had to live laborious days and the majority required further training afterward. Diagnosis was the keystone of the arch of medical training. There could be no giving way on the essential point that knowledge of diagnosis must precede the power to treat. The bill would give a short cut to a body of people who wanted the status of physicians. If that kind of training should be allowed to displace the scientific training which could be built up only by years of experience if any short cut or back door entrance should be allowed, the whole fabric of the efficiency of the healing art would be brought down from the level it had taken years to build up. Physicians were prepared to treat osteopaths as co-workers but not to give them equality of status in the science of medicine for which they did not have the proper training. For osteopathy to have the status of medicine without the training in pathology would be a public danger. The danger of uncontrolled and ungoverned crafts was that they began well and in their own sphere did admirably but grew like a snowball and one did not hear of the infinite damage they did. Osteopathy could be a perfect terror and a tragedy, as he himself knew.

Lord Hewart (lord chief justice) said that the bill would allow an osteopath to issue a death certificate and as a mere lawyer he was staggered at that proposal. For the government Viscount Gage said that there was nothing today to prevent an osteopath from treating a patient and receiving a fee. A patient might have a complaint with which an osteopath was especially competent to deal, but if he had something more deep seated the osteopath might have no qualification for diagnosing it. If the bill became law the patient would be protected against the absolutely ignorant practitioner, but his complaint would still be diagnosed by somebody who possessed a good deal less than the minimum qualifications at present. In spite of the opposition of the government the motion for rejection of the bill was negatived by 35 votes to 20 and the bill was read a second time.

It must be remembered that in spite of the arguments of the ablest advocates in the profession and the opposition of the government, this success of the osteopaths was obtained in a very small house. The result means simply that the supporters of the bill were able to muster a larger number of votes than those who could be induced to attend to oppose it. The small number who supported the bill can be explained by the support that irregular practitioners always receive in this country, often from those in high social position, who seem as amenable to quackery as any class. The success or apparent success of treatment by osteopaths when orthodox treatment has failed is noised about and considered a crucial test. The cogent arguments as to the danger of recognizing an inferior order of medical practitioners were ignored and the opposition to the osteopaths' proposal was represented as professional jealousy and not regard for the public welfare.

The Locust Plague in South Africa

The locust plague has been exceptionally severe all over South Africa this year. Trains from the north are being regularly delayed for from one to two hours. Locusts congregate, covering the rails to a depth of 6 inches, and as they are crushed they make the rails slippery and bring the train almost to a standstill. The government is pursuing an energetic poisoning campaign, but although the northwest has been almost cleared little headway is being made in the midlands. The antilocus measures have their drawbacks. The standard method is spraying with sodium arsenite but when the same area is sprayed again and again to cope with fresh hordes, the grass becomes poisoned and cattle grazing on it die. Wild birds eat

the poisoned locusts and die, and as they are the farmer's first line of defense against locust and other insect pests their destruction is beginning to alarm both farmers and naturalists. Already locust swarms have penetrated within 100 miles of Capetown and it is possible—unless strong southeast winds sprung up and blow them back—that they will reach the front and win wars with disastrous results. Provision has been made for two special poison-spraying trains to patrol the line between Bloemfontein and Naauwpoort. By the use of hose pipes the locusts are sprayed for some distance on each side of the line and innumerable swarms destroyed. At times for stretches of 9 miles hoppers moved in mass across the lines and for nine or ten hours daily the poison trains moved up and down these sections. In one section the hoppers were seen covering an area of 15 by 6 miles in one solid mass.

Tetanus from Toy Pistols

In an annotation in the *Times* on toy pistol tetanus the statement was made that the conveying of the disease by the cartridges was an unproved hypothesis. Dr. James McIntosh of the Bland-Sutton Institute of pathology has therefore pointed out that some recent investigations carried out there show that the infection can be conveyed by the cartridge, the wad in particular. Observations made on material from three cases of toy pistol tetanus showed that, in two, pathogenic strains of the bacillus of tetanus were present in the wad of the cartridge. In each instance pure cultures were ultimately isolated. In the last case pure cultures were obtained from five out of six cartridges taken at random from the box used by the patient. The infection is contained in the hairlike felt of the wad, as cartridges containing paper wads were never found infected with the bacillus, nor were the metal case or powder.

Apparently the discharge of the pistol is the determining factor. When the pistol is fired there is a great tendency for a finger or part of the hand to come close to the hole in the top of the pistol through which the products of the explosion are discharged. When this happens a deep lacerated wound is produced, into which are driven particles of the infected wad. The necrotic material in such a wound is an ideal medium for the rapid growth of the bacillus. The lines along which measures of protection should be taken are thus indicated.

Hemorrhage as First Symptom of Latent Amebiasis

The atypical types of amebic intestinal infection are beginning to attract more and more attention on the part of clinicians. Anglade and Rosenbach have just reported three cases from an army hospital, of a clinical type of amebiasis that had previously been reported by Rachet in 1927. This latent form of amebiasis presents as its first clinical evidence a sudden severe hemorrhage from the intestine. In none of the three cases reported was there the least suspicion of the amebiasis before the enterorrhagia. In all three, evacuations had been normal previously. It was only after the examination of the stools that the dysenteric ameba was found as the etiologic factor, hence such an examination ought to be made in every case of symptomless intestinal hemorrhage. None of the three patients had ever lived in the colonies, where amebic dysentery is not so rare.

Prophylaxis of Typhoid, Undulant Fever and Diphtheria

In his annual report to the Academy of Medicine, November 13, Dr. Louis Martin, director of the Pasteur Institute, presented some interesting observations. Only 10,657 of the 38,007 cities and villages of France have a pure water supply.

Absence of *B. coli* in the reservoirs is not sufficient proof of purity. Bacteriologic examination should also be made of the water as it comes from the faucets. Many cases of typhoid occur during the summer vacation period. The water of Paris and other large cities of France is pure, but this is not always the case in the resorts to which one goes for a vacation.

Undulant fever, which was reported in 1925 from only seventeen departments of France, now exists in fifty-seven.

Milk from goats and sheep and cheese made from milk of these animals, which is consumed in many parts of France, can be considered responsible in only a small number of cases, but the disease frequently appears in severe form in cattle breeders and in farmers in the south of France. A polyvalent vaccine has been tried, but it is evident that more effective prophylactic measures must be employed to control this constantly increasing menace to the agricultural districts.

As regards diphtheria, Dr. Martin stated that in the majority of reports one finds a decrease in frequency of the disease and that vaccination with anatoxin has been well received. There are some children who can be vaccinated only with difficulty and it requires much persuasion to convince the parents that it must be repeated. This is not necessary at the beginning of an epidemic, because the parents all demand that vaccination should be done as soon as possible.

Antidiphtheria vaccination is not followed by marked reactions, but several cases of abscess formation have occurred, and there were two deaths. For the latter, the anatoxin was found not to be responsible, however. In the department where the large city of Lyons is located, one found that there was a marked decrease in the morbidity whenever two thirds of the children had been vaccinated. If only half were vaccinated, there was little change in the morbidity. Some cases of diphtheria have been reported in children who had been vaccinated, but even so the attack is usually a very mild one, though death may occur if the antitoxin is not given early enough. One can explain these cases of diphtheria in those who have been vaccinated through their being refractory or because only a single injection of the anatoxin was given. There are also children who do not form antibodies. If a vaccinated child presents the clinical signs of a diphtheria, one should administer treatment without waiting for the bacteriologic report. Dr. Martin believes that vaccination with the Ramon anatoxin should be made obligatory, preferably when the child is a year old. A committee was appointed by the Academy of Medicine to study the entire question of antidiphtheria vaccination.

Senile Dwarfism or Progeria

There is a special form of infantilism which is not as rare as was at first believed. It was first described by Variot of France in 1910 and the term progeria was applied by an American author, Gilford, at about the same time. The condition is found in children and adolescents who present the appearance of the aged. One of the chief characteristics, according to an article by Barraud in the *Gazette médicale*, November 15, is the emaciation due to almost complete disappearance of the subcutaneous adipose tissue especially in the face.

In most cases there is absence of the eyebrows and eyelashes. The skin is parchment-like, with visible subcutaneous vessels. There is deformity of the heads of the femurs and absence of development of secondary sexual characteristics. The disease usually appears about the third year of life, so that at the age of 18 to 20, the boy or girl looks like a child of 5 or 6 and has about the weight corresponding to the latter age. Only two necropsies have been reported, one by Gilford and the other by Orrico and Strada (1927). Gilford found sclerosis of the viscera with markedly thickened capsules as in the aged, also atheromatous plaques in the aorta, cardiac valves and coronary arteries. The suprarenals were decreased in size but normal.

There was a marked hypertrophy of the thymus, which was about twice as heavy as the normal gland. Orrico and Strada found a marked lack of development of the suprarenals, thyroids, parathyroids and testes, and an advanced sclerosis of the aortic and other large vessels, but the pancreas and thymus were normal. Radiography in these progeria (premature senility) cases reveals disturbances of ossification of the epiphyses. In the author's case there was marked improvement both in weight and in growth following the use of ultraviolet rays and opotherapy (polyglandular).

The Dissension Over Reconstruction of the Studentenschaft

The difficulties that persist in the studentenschaft and have been brought into that organization mainly by the National Socialist party have been reported before (*THE JOURNAL*, Sept. 29, 1934, p. 1004). This development has progressed with rapidity and has led to noteworthy results. The prerequisite of a half year of compulsory labor for students demanded for matriculation in a German university was to be accomplished this year from May 5 to October 25 by four months of labor service and six weeks of sport activities in the country. Foreigners and "non-Aryans" are excluded, whereas German matriculants residing abroad may participate although they will not be forced to take part, these are children of parents who, though German in origin, have their residence abroad. Exceptions are made of unfit individuals, of students of Catholic theology (who may participate if they choose to do so) and of those whose course of study is preceded by at least a year of practical work, during which time the person concerned does physical labor in the company of ordinary workers and associates and fraternizes with the workers outside of working hours. This work service is compulsory only for students. A voluntary choice of work service has as yet still been maintained for others. If their conduct bears satisfactory testimonial, the young people engaged in this fun called "work" will be granted special favors in case of new positions. This fact will prove a disadvantage to the progress of those excluded from participation. The work service certainly offers definite training effects. In addition, "political science education and training" are on the education program. According to the plan of Feikert, leader of the reich's students organization, after the young student has received the desired training from the Hitler youth, the storm troops and the work service, he brings this new form of life with him to the university. Feikert published a decree in September before the beginning of the present winter semester on the communal training of the studentenschaft. This decree subjects students to a National Socialist military drill. The most important provisions of the decree are the following:

After satisfactorily completing his work in the compulsory work service, the student must study at the same university for two semesters. During this time he is compelled to live in one of the "community houses" conducted by the National Socialist party and recognized by the studentenschaft. (These community houses, kameradschaftshäuser, are houses in which the communal spirit and fraternizing of the labor camps will continue, the object being to erase class distinction and provincial allegiance as opposed to national allegiance from the minds of the students and to further the interests of totalitarianism.) Here the young students are given an intensive training along National Socialist lines. Older students may be admitted to the kameradschaftshaus only if they belonged to the National Socialist organization before Jan. 31, 1933, or if since that time have been active in the National Socialist reconstruction pro-

gram The inhabitants of each kameradschaftshaus must wear uniform dress The small cap and ribbons, the insignia of the German student fraternities, cannot be worn by them during the first two semesters Feikert may install and dismiss the directors of each kameradschaftshaus at will, moreover, he exercises the same right in the student corporations and societies Through such measures the breeding of a uniform type of student will naturally become more and more complete For the law student there is the added pleasure of a stay in a "jurisprudential training camp," which he must attend between the time of his final university examination and the state or bar examination In these compulsory provisions the student leader exceeded any measure that could be tolerated by those concerned The fraternities, those traditional organizations of German students, felt threatened by these measures, which were undoubtedly directed against some of the fraternities according to remarks made by Feikert in a radio address Bitter opposition arose headed by Lammers secretary of state in the federal chancellory, who became the protector of the fraternity students The mentioned decree was disapproved of by the highest office in the government, and so the student leader had to revise it and delete the most essential clauses after it had already been in operation The first of these "student leaders," Dr Stabel, had to be dismissed because he was accused of lack of resolution, whereas his successor destroyed his own work by excessive energy The student fraternity corps became more firmly entrenched Training in the kameradschaftshaus with all its attendant results of uniformity has now become a matter of choice, no force with respect to joining these houses may be exercised either on the fraternities or on individuals There is no longer any talk of dissolving individual student corporations, which Feikert had expressed himself as intending to do

The corporations likewise took a stand against the totalitarian onslaught They protected themselves courageously against verbal attacks, provocation and actual assault This happened for example, in Bonn, where the students in their caps and colors were jostled by the Hitler youth The students of these fraternities (korps) had been considered for a long time as reactionaries, they had been following a political course to the right for quite a while and were, accused of bourgeois class prejudice and similar things by the Hitler youth They are protecting themselves with all their might against such accusations The well known play "Old Heidelberg" had to be taken off the list of performances by the order of one student leader because it did not conform to the type of present-day German students That is quite true and since that day the play has been dubbed "sentimental tripe." It is, however, more significant from the difficulties brought forth by the attempts at totalitarianism that a rift has resulted among the fraternity students All student corporations have patterned themselves according to National Socialist principles and to a great degree are controlled by the party Nevertheless there is a marked difference between the korps and the other "fighting" societies holding duels The korps have founded training camps especially for the leaders of individual societies (seniors and presidents of student classes) in which discussions on the formation of studies, student storm troop service and numerous other questions are taken up Nevertheless, the korps are striving more than the other student organizations to preserve their tradition They are often reproached for not enforcing the "Aryan principle" on their alumni that is to drop all present and past members having Jewish blood even beyond the third generation (beyond the grandmother clause) They are also reproached for being negligent in weeding out all Free Masons The same contention applies to all members who have acquired

Jewish connections by marrying a not purely "Aryan" woman The korps have compelled a few of these older members not to resign on the basis of their having fought in the war, while the other organizations take an irreconcilable attitude toward the Jewish question These differences have led to open enmity between societies that had always been joined in one intramural dueling group A common political point of view does not exist, for the burschenschaften demand an uncompromising adherence to the lines of the National Socialist party The National student leader is also seeking to regulate the direction of scientific effort He has carefully defined the prerequisites for scientific work in the face of the general decline of the universities and of liberal scientific pursuits A session of the German National Students Association in the spring of 1935 will summarize the potentialities in the younger faculty members and in the students for a permeation of the universities with the political ideas of National Socialism The stand taken by the older men with respect to the present direction of scientific effort may be seen from the following quotations The conference of rectors (after the Nazi revolution all rectors of universities were either replaced by Nazi men or were reinstated as suitable to the party) of Prussian universities several months ago declared that the rectors were "convinced of the necessity of internal change in the direction of scientific efforts and of the university along the ideas of National Socialism"

National Socialism is the only living and creative power which frees the development of the mind and the university from purely specialist, theoretical and technical minute divisions" The national commissioner of justice, Dr Frank, has demanded that intellectual workers "should not strive primarily for self recognition but they must always ask themselves the question Does my scientific training serve the cause of National Socialism above everything else?" At a recent philological congress it was demanded that intellectual objectivity must give way before political subjectivity The representatives of the new National Socialist system of thought are opposed, however, by a large number of men who unwaveringly adhere to the tradition of objective science even if they do not make public declaration of the fact

It is significant that even the leader of the discussion, the chief clerk of a ministerial department and therefore an official personality, objected to the "abolishment of hypothetical processes in science." The new chief of the Public Health Office of Bavaria, Dr Walter Schultze, previously a practicing surgeon, now ministerial director and professor at the University of Munich, also expressed himself in the same way At the last National Socialist Bavarian Physicians Congress he remarked that the statement "lack of hypothetical processes in science" arose from the same trend of aberrant scientific work and of human conceit, he cites, as an example, the objection made by a physicist to the existence of the so called earth rays Recently at the Congress of German Biologists and Physicians "a group of older representatives from every possible field of science were trying to accept this erroneous impression—one and three fourths years after the National Socialist revolution"

The university became more or less of a bureaucratic establishment which was neither in a position nor possessed the power to build personalities but at its best produced, in the last analysis, an army of statisticians" In order to appreciate the work of the future medical profession, it is most important to understand the new direction of the academic profession and the present makeup of the university Only those who have the talent and power to inculcate the leader principle into their students may become university instructors in the future The number of students to become physicians must be considerably limited their qualifications for the profession must be tested constantly not only by examinations but by repeated experi-

ments, by keeping a close check on the entire course of study and by demonstrations of character

These are the latest principal facts and statements from authoritative sources, which may contribute to the general picture of the type of education and the interpretation of the sciences in Germany today. There are, undoubtedly, some retarding influences and much of what is being said may be attributed to oratorical license. These sketches indicate the direction desired by the group in power which will bring outside force to bear in order to push its plans through.

MEXICO

(From Our Regular Correspondent)

Nov. 30, 1934

Educational Improvements in Mexico City

The government of Mexico celebrated the anniversary of the Mexican revolution November 20, with the following ceremonies. 1 The inauguration of a grammar school in Belem with a capacity for 10,000 children. The establishment of this school symbolizes the trend of the government to prevent the spreading of evil by giving the new generation education, an opportunity not previously provided to the people. Nowadays schools are opened all through the country. It shows also the control of the government on crime which permitted the demolition of the old dark Belem jail and the construction on the same grounds of a modern school. The Belem jail from colonial days until its demolition was a focus of epidemic typhus, which frequently spread all over the city, and a breeding place for rats, a large percentage of which were either sick or heavily infested by *Rickettsia prowazekii*. 2 The inauguration of improvements at the Juarez Hospital. The old church of San Pablo joined to the hospital, was reconstructed and divided into several entirely independent departments: an assembly hall with a medical library, a large chapel, an amphitheater for necropsies, a laboratory, and refrigeration chambers accommodating twenty cadavers. In the hospital, wards were provided for emergency patients, a hair-dressing room was opened, baths were installed, offices were supplied for physicians and for consultation and departments inaugurated for the treatment of diseases of the eyes, nose and throat and for stomatology, gynecology, obstetrics, the digestive tract, bones and joints, neurosurgery, urology, x-rays and laboratory work. 3 Unveiling of a memorial plate in honor of Benito Juarez.

New Regulations for Antituberculosis Dispensaries

The department of public health has issued detailed regulations on the organization and functions of antituberculosis dispensaries, which aim to secure uniformity in the organization and services given. The dispensaries are concerned, according to the new regulations, with the detection of tuberculous patients, the investigation of the reports of visiting nurses, the diagnosis of the disease by physicians in the dispensaries, the hygienic education of patients and their families, the sanitation of houses and preventive vaccination. There will be central dispensaries in the capital of every state, with branches in some cities. Every central dispensary will be under the control of the general committee of the antituberculosis campaign. All the dispensaries will be provided with a waiting room, two wards, departments for radioscopic laboratory, and otorhinolaryngologic services, offices for the director and the general manager, and a storeroom. The personnel in every central dispensary will include a head physician who will also be in charge of a clinical ward, an assistant physician, two interns, a head nurse, two student nurses and as many visiting nurses as necessary to cover the work of the given territory, a technician, bacteriologist, a janitor, two porters, a watchman, and physicians specializing in otorhinolaryngology, radiology and bacteriology.

Marriages

MAX EVANS WHICKER, China Grove, N. C., to Miss Thelma Adelaide Wilkerson of Prospect, Va., in Lynchburg, Va., recently.

RUSSELL ROBERT RICHARDSON, Monon, Ind., to Miss Mary Elizabeth Rickards of Decatur, Ill., in Indianapolis, Dec. 6, 1934.

LOUIS BLANCHARD WILSON, Rochester, Minn., to Miss Grace Greenwood McCormick of Pittsburgh, January 2.

HAROLD WILLIAMS WILEY, Lansing, Mich., to Miss Luverne Elizabeth Herst of Grand Rapids, Dec. 1, 1934.

WEBSTER BRIDGES KEY, Memphis, Tenn., to Miss Mary Elizabeth Fry of Union City, Nov. 28, 1934.

DENNIS CARNEGIE STODENMIRE, Honea Path, S. C., to Miss Eva Hagan of Due West, Nov. 3, 1934.

CYRUS G. REZNICHEK, Antigo, Wis., to Miss Sara Marie Zanna of Gilbert, Minn., Nov. 6, 1934.

JOHN SMITH NEWMAN, McRoberts, Ky., to Miss Billie Sue Brae of Rome, Ga., Nov. 18, 1934.

THOMAS FLOWMAN SPARKS, Vicksburg, Miss., to Miss Gladys Clement Dec. 3, 1934.

JOSEPH M. HARRIS, Los Angeles, to Miss Elinor Rosenwald of Chicago, January 2.

Deaths

Lewis Stephen Pilcher, Upper Montclair, N. J., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1866, adjunct professor of anatomy, Long Island College Hospital, Brooklyn, 1879-1883, professor of surgery, New York Post-Graduate Medical School, 1885-1895, in 1892 president of the Medical Society of the State of New York, in 1900 president of the Medical Society of the County of Kings, member and past president of the American Surgical Association, fellow of the American College of Surgeons, member of the state board of medical examiners, 1913-1928, Civil War veteran, surgeon general of the Grand Army of the Republic in 1915 and commander in chief in 1921, surgeon to the Methodist Episcopal Hospital, Brooklyn, 1887-1907, German Hospital, Brooklyn, 1900-1908 and owner of a private hospital bearing his name 1910-1918, at various times on the staffs of the Wyckoff Heights Jewish, Bushwick, St. John's, Norwegian and Bethany Deaconess hospitals, Brooklyn, founder and editor of *Annals of Surgery*, co-author of the "American Text-book of Surgery" and other works on surgery, aged 89, died, Dec. 24, 1934, of arteriosclerosis.

Jacob Geiger, St. Joseph, Mo., University of Louisville (Ky.) Medical Department, 1872, professor emeritus of surgery, St. Louis University School of Medicine, dean and professor of surgery, ENSWORTH Medical College, 1883-1914, past president of the Missouri State Medical Association and the Missouri Valley Medical Society, fellow of the American College of Surgeons, in 1884 president of the city board of health, president of the city council of St. Joseph, 1886-1888, formerly bank president, president of the board of managers of the State Hospital, number 2, 1910-1914, on the staff of the Missouri Methodist Hospital, aged 86, died, Dec. 8, 1934, of coronary occlusion.

Katherine Weller Dewey, Pittsburgh, Rush Medical College, Chicago, 1912, associate professor of clinical pathology, University of Pittsburgh School of Dentistry, formerly assistant in obstetrics and gynecology and fellow in pathology at her alma mater, at one time research assistant in the department of histology and oral pathology, and assistant professor of oral pathology, University of Illinois College of Dentistry, Chicago, associate editor of the *Journal of Dental Research* and co-author of a textbook called *Pathology of the Mouth*, aged 66, died Nov. 11, 1934, in Bad Nauheim, Germany, of carcinoma of the stomach.

Edward John Hussey, Holyoke, Mass., Harvard University Medical School, Boston, 1904, member of the American Academy of Ophthalmology and Oto-Laryngology, the New England Ophthalmological Society and the New England Otolological and Laryngological Society, fellow of the American College of Surgeons, served during the World War on the staffs of the Holyoke Hospital and the Providence Hospital, aged 61, died, Dec. 4, 1934, of bronchopneumonia.

Henry Byrd Young, Burlington, Iowa Chicago Medical College, 1875, member and past president of the Iowa State Medical Society, past president of the Des Moines County Medical Society, member of the American Academy of Ophthalmology and Oto-Laryngology, aged 83 at various times on the staffs of St Francis Hospital Burlington Protestant Hospital and the Mercy Hospital, where he died, Dec 10 1934, of uremia

Michael Francis McGuire @ Montpelier, Vt University of Vermont College of Medicine, Burlington 1895 past president of the Vermont State Medical Society member of the state board of medical examiners member of the New England Surgical Society, fellow of the American College of Surgeons on the staff of the Henton Hospital aged 66 died Nov 20, 1934 of myocarditis and arteriosclerosis

Emmett Terry Wickham, Waterloo, Iowa State University of Iowa College of Medicine Iowa City 1888 Bellevue Hospital Medical College, New York 1891 member of the Iowa State Medical Society past president of the Washington County Medical Society, served during the World War aged 67, died, Dec. 6, 1934, of heart disease

John Francis Healey @ Buffalo University of Buffalo School of Medicine, 1916 member of the American Academy of Ophthalmology and Oto-Laryngology served during the World War, on the staffs of the Buffalo City Hospital Buffalo General Hospital and the Childrens Hospital, aged 41 died, Nov 30, 1934, of coronary sclerosis

Joseph Patrick Francis Burke, Buffalo, Niagara University Medical Department Buffalo, 1896 served during the World War, formerly on the staff of the Buffalo Hospital of the Sisters of Charity and the Emergency Hospital of the Sisters of Charity founder of the Central Park Clinic aged 60, died, Dec. 14 1934, of myelitis

Paul Hamlin Faucett, Columbia, Tenn Barnes Medical College, St Louis, 1908, member of the Tennessee State Medical Association, past president of the Maury County Medical Society, served during the World War on the staff of the Kings Daughters' Hospital aged 49, died, Dec 8 1934, of pneumonia

Saul Rutstein, New York, Columbia University College of Physicians and Surgeons, New York 1921 aged 37, on the staffs of the Mount Sinai Hospital, Peoples Hospital and the Lebanon Hospital where he died Nov 30 1934, of chronic rheumatic heart disease and bronchopneumonia

John Lindley Henry, Athens, Ohio Columbus Medical College, 1891, member of the Ohio State Medical Association past president of the Athens County Medical Society on the staff of the Sheltering Arms Hospital aged 68, died Dec 7, 1934, of acute cholecystitis and nephritis

Alfred Davis Wetherby @ Middletown, Ky, University of Louisville School of Medicine, 1924 aged 35 died Dec 11 1934 in the Kentucky Baptist Hospital, Louisville, as the result of injuries received when the automobile in which he was driving was struck by a train.

John George Miller @ Lancaster N Y University of Buffalo School of Medicine, 1876, Bellevue Hospital Medical College, New York, 1877, for many years president of the board of education and bank president aged 79, died, Dec. 6, 1934, of carcinoma of the bladder

Franklin Willard Freeman, Lynnfield Center Mass University of Vermont College of Medicine, Burlington 1889 member of the Massachusetts Medical Society aged 74, died Dec 5, 1934 in the Palmer Memorial Hospital, Boston of diabetes mellitus

Lee Cowan @ Atchison, Kan Ensworth Central Medical College, St Joseph, Mo, 1906, past president of the Atchison County Medical Society, on the staff of the Atchison Hospital aged 52 died suddenly Dec. 9, 1934, in St Louis of heart disease

Frederick Clayton Thiede, Grand Rapids Mich. Detroit College of Medicine and Surgery 1914 aged 45 died Dec 18, 1934, in St. Lawrence Hospital Lansing of injuries received when the hotel in Lansing where he was staying caught fire.

Fred Kirschenbaum, Brooklyn Long Island College Hospital Brooklyn, 1906, on the staffs of the Israel-Zion Hospital the Harbor Hospital and the Brooklyn Eye and Ear Hospital aged 51, died suddenly, Dec. 11 1934 of heart disease

John Geikie Adam @ Great Barrington Mass., Trinity Medical College, Toronto Ont., Canada 1900 served during the World War, aged 56, died Dec 1 1934, in Fairview Hospital of mesenteric thrombosis following a cholecystectomy

Ernest Lightfoot Strader, White Bear Lake, Minn., Hospital College of Medicine, Louisville, Ky, 1902, formerly superintendent of the Deerwood (Minn) Sanitarium, aged 58 died Nov 6, 1934, of cerebral arteriosclerosis and nephritis

James P Dunigan, Sullivan, Mo., Missouri Medical College St. Louis, 1885 member of the Missouri State Medical Association, past president of the Franklin County Medical Society aged 75, died, Dec 2, 1934, of uremia

True Edgecomb Makepeace @ Farmington, Maine, Bowdoin Medical School, Portland 1917 served during the World War on the staff of the Franklin County Memorial Hospital, aged 43 died Nov 6, 1934 of myocarditis

William N Bailey, White Plains Ky, University of Tennessee Medical Department, Nashville, 1884, member of the Kentucky State Medical Association, aged 76, died Dec. 18 1934, in Louisville of cerebral hemorrhage

Benjamin May Baker, Norfolk, Va College of Physicians and Surgeons, Medical Department of Columbia College New York 1889 member of the Medical Society of Virginia, aged 69 died Nov 16, 1934 of uremia

John Calvin Young @ Ozark Mo St Louis College of Physicians and Surgeons, 1898, past president of the Christian County Medical Society, owner of the Ozark Sanitarium, aged 74 died Dec 7, 1934 of heart disease

Ellis Herbert Whitehead, Brookings, S D State University of Iowa College of Medicine, Iowa City, 1904 served during the World War, aged 66, died, Dec. 19, 1934, in Sioux Falls of carcinoma of the pancreas

Barbour Dicks Cooper @ Mansfield La Vanderbilt University School of Medicine Nashville Tenn 1888 on the staff of the Mansfield Sanatorium, aged 67, died, Oct 19, 1934, of aneurysm and coronary thrombosis

Cephas T Dodd @ Washington, Pa Western Reserve University Medical Department, Cleveland, 1881, past president of the Washington County Medical Society, aged 80, died, Oct 28, 1934

Emma Hortense Gabel, Chicago, Northwestern University Woman's Medical School, Chicago, 1900, aged 73 was found dead Dec. 19, 1934, of chronic nephritis and arteriosclerotic myocarditis

Jesse B Thompson, Atlantic City N J, University of Pennsylvania School of Medicine Philadelphia, 1888 formerly bank president, aged 77, died, Nov 18, 1934 of carcinoma of the bladder

George Healy Davis, Springfield, Mass College of Physicians and Surgeons, Baltimore, 1897 aged 84 died, Oct. 28, 1934, in the Northampton (Mass) State Hospital, of arteriosclerosis

Cecil Carrie Kellam, Port Blakely, Wash, Willamette University Medical Department, Salem, 1889, member of the Washington State Medical Association, aged 69, died Dec 7 1934

Charles H Kisner, Oblong, Ill, Medical College of Indiana, Indianapolis, 1895 member of the Illinois State Medical Society, aged 69, died, Nov 17, 1934 of angina pectoris

Mark W Harrison, Shadypoint, Okla Arkansas Industrial University Medical Department Little Rock, 1898 aged 76, died, Nov 11, 1934, of fibroid tuberculosis of the lungs

Louis Howe, Cody, Wyo, Medical College of Ohio Cincinnati, 1879 member of the Wyoming State Medical Society, aged 80, died Nov 20, 1934, of arteriosclerosis

Melvin Oliver Swan, Big Stone Gap, Va. (licensed in Virginia under the Exemption Law of 1895) aged 73, died, Nov 19, 1934, of diabetes mellitus

Perrin P Johnson, Bentonla, Miss (licensed in Mississippi in 1908), aged 64, died, Nov 15 1934, of cerebral arteriosclerosis and chronic myocarditis

Thomas Jefferson Hunter, Trenton S C Louisville (Ky) Medical College, 1891, aged 73, died, Nov 23, 1934, of arteriosclerosis and myocarditis

Charles A Barber, Hattiesburg, Miss, Missouri Medical College, St. Louis 1884, aged 81, died, Nov 29, 1934, of nephritis and pneumonia.

Fred O Bartlett, Rockland Maine, University of Vermont College of Medicine, Burlington, 1887, aged 79, died, Dec. 7, 1934, of heart disease

Oliver R. Edmonds @ Tina, Mo, Marion-Sims College of Medicine, St. Louis 1896 aged 70, died, Nov 18, 1934, of coronary thrombosis

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

CITRUS FRUITS AND DERMATITIS

To the Editor—I have a patient who shows a dermatitis on her hands soon after the ingestion of any of the common citrus fruits such as lemons, oranges, limes or grapefruit. Is it possible to desensitize this person? If so kindly give details of such procedure. If this query is published, kindly omit name and address. M D North Dakota

ANSWER—This query brings up the relationship between contact dermatitis and allergic or atopic eczema. Sufficient evidence is now at hand to enable a clear-cut differentiation, at least theoretically. It is sometimes difficult to separate the two conditions practically, because an exciting agent may act in both ways in some instances. Thus, silk may cause a dermatitis or urticaria by inhalation, it is thought, there can be little doubt that it can also cause an eruption of the skin by direct contact. Citrus fruits (orange, lemon, lime and grapefruit) can likewise cause a skin condition by ingestion; in addition, contact with the peels of these fruits is a frequent cause of dermatitis.

In this case the question Which is the method of action? comes up. To differentiate, if the dermatitis is due to ingestion of the fruit there will usually be found one or more of the following: (1) a history of some allergic condition in other members of the family, especially a parent, (2) some other allergic condition in the patient, e. g., hay fever, bronchial asthma, food upsets with gastro-intestinal symptoms or migraine, (3) a blood eosinophilia, (4) relief by the injection of epinephrine, (5) positive skin tests cutaneous or intracutaneous, (6) a positive passive transfer (Prausnitz-Küstner phenomenon). It is not necessary that all these be present. The protein in the fruit is the exciting factor (allergen or atopen).

On the other hand contact dermatitis is characterized by (1) absence of allergy in the family, (2) absence of other allergy in the patient, (3) no eosinophilia in the blood, (4) no relief by epinephrine, (5) negative skin tests, (6) negative passive transfer and (7) positive contact or patch tests, which in most cases can be obtained by laying pieces of the peel against the skin and leaving them in place for from twelve to seventy-two hours.

All the recent literature tends to incriminate the oily fraction of the peel, not the protein, as the cause of the trouble. This is in accordance with the now established fact that it is the oily fractions of ragweed and other weeds and plants that cause the cases of contact dermatitis; the protein is not a factor in these instances. It is well known, of course that the protein fraction of the pollen of these weeds is largely, if not entirely, responsible for the symptoms of pollen hay fever and asthma.

As to treatment if the diagnosis is contact dermatitis to peels avoidance should be sufficient, rubber gloves may be necessary. If not sufficient, desensitization may be tried by increasing injections of extract of the oily fraction of the peels. If the condition is one of allergic or atopic dermatitis or eczema, avoidance of ingestion is essential. If thought advisable the patient may be desensitized either orally or hypodermically. Orally orange juice, for example, may be given in increasing amounts one drop of orange juice in a glass of water the first day then two, three, and so on. Hypodermically injection of a dilute extract of orange juice protein e. g., 1:10,000 with increasing dosages until a strong extract e. g., 1:100 is reached then orange juice can be added in increasing amounts. The other fruits may be administered in a similar manner. Injections of protein extracts will not help cases of contact dermatitis. Injections of oily extracts will not help patients who suffer from allergic dermatitis.

CLOSURE OF FONTANEL

To the Editor—I have recently been informed by a pediatrician that the opinion as regards the normal time of complete closure of the anterior fontanel has undergone a change namely that early closure at the fourth or fifth month is now considered to be entirely normal. I would appreciate your view on this matter. Also has the liberal use of vitamin D in cases not markedly rachitic any bearing on the question? Please omit name. M D New York.

ANSWER—The time of complete closure of the anterior fontanel is subject to considerable variation in normal infants. The postnatal involution goes on steadily in normal infants although at widely varying rates in different individuals and apparently more rapidly in girls than in boys. The material quoted in textbooks on which average time of closure is based

was obtained to some extent from the poorer classes of larger American and European cities. An average figure of these data is 0.3 per cent from 3 to 6 months of age. It is probable that the percentages of obliteration are somewhat low for better nourished and more rapidly growing American children. However, it is safe to say that a small percentage of apparently normal children show complete obliteration of the anterior fontanel in the first year of life. From this time on the time of obliteration increases markedly, so that by the eighteenth month the majority are closed. In some of the cases in which closure of the anterior fontanel takes place during the first year, a separate ossification center may arise in the fontanelar membranes and form distinct bone, which may occupy a part or all of the original fontanelar space. With regard to the effect on the time of closure with the liberal use of vitamin D in cases not markedly rachitic, the data of Julius Hess and his associates (*THE JOURNAL*, Aug. 2, 1930, p. 316) may be quoted. From their data they concluded that (1) ordinary doses of viosterol (comparable to the present 250 D) up to 20 drops daily had no effect on the rate of closing of the fontanel but that massive doses, above 210 drops a day, hasten the closure of the fontanel to a moderate extent.

DIFFERENTIAL DIAGNOSIS OF APPENDICITIS IN PUERPERIUM

To the Editor—Please give the differential diagnosis between acute appendicitis ruptured and coming on the following day after a normal delivery resulting in the formation of an abscess and puerperal sepsis developing the following day after a normal delivery and resulting in an abscess. Please give medical and surgical treatment for both. Please omit name and city address. M D, West Virginia.

ANSWER—The differentiation of acute appendicitis from the onset of sepsis the day following delivery should not be difficult. A history of previous attacks of appendicitis especially during the pregnancy in question may be of some assistance. However, when symptoms of acute appendicitis set in the day after childbirth, the chief argument in favor of this diagnosis is the fact that sepsis, especially with abscess formation, rarely starts within such a short time after the birth of a baby. Furthermore, the symptoms of the two illnesses are generally different. In favor of acute appendicitis are the following signs and symptoms: an acute onset of pain which first centers around the umbilicus and then localizes in the right lower quadrant, pronounced tenderness which is higher than McBurney's point because of the enlarged puerperal uterus, vomiting as a rule, and definite muscular rigidity in the right lower quadrant. In sepsis the onset is not as dramatic as it is in appendicitis and if it is fulminant it rarely results in the formation of an abdominal abscess, because it is usually fatal before an abscess can form. On the other hand, in long drawn out puerperal sepsis cases in which there is pyemia, abscesses may be found almost anywhere in the body, within serous cavities as well as in superficial parts. In a large proportion of cases of acute sepsis, pathologic organisms may be detected in blood cultures, especially if large amounts of blood are used for the cultures. The lochia may show the same organisms as are found in the blood. In most cases in which sepsis sets in early after delivery, there has been evidence of infection during labor. Puerperal appendicitis and puerperal sepsis may exist at the same time. Perforation of the appendix with or without the formation of an abscess during pregnancy or the puerperium is a much more serious condition than it is in the nonpregnant state. The reasons for this are as follows: The soft enlarged puerperal uterus moves about more or less freely and interferes with the safe localization of an abscess. It usually prevents abscess formation in the pelvis where the body can better withstand infection than in the upper part of the peritoneal cavity. There is greater absorption of bacteria and toxic products due to the intense congestion in the lower part of the abdomen and pelvis, and thrombosis and phlebitis occur more often. Bacteria in the blood may invade the freshly wounded uterine endometrium especially the placental site, and lead to puerperal infection.

The treatment of an abscess due to either acute appendicitis or puerperal sepsis is not simple unless the abscess is situated in the culdesac. In such a case a simple colpotomy, with the insertion of a large rubber T-tube, will usually secure most satisfactory results. If the abscess is not located in the culdesac but is in the broad ligament, a gridiron incision should be made above Poupert's ligament. This will drain the abscess extraperitoneally. If the abscess cannot be reached through the culdesac or extraperitoneally, the abdomen will have to be opened and the abscess cavity drained in this way. This procedure is the most dangerous of the three operations. Naturally the patient should be isolated before and after operation. Every

effort should be made to build up her resistance by supplying proper food, fluids, fresh air, sunlight, sedatives for pain, soporifics for sleep and blood transfusions when necessary. After operation, the head of the bed should be elevated to favor drainage from the abscess. Ergot should be given to keep the uterus contracted, but some of the constituents of the drug may also have a beneficial effect on the reticulo endothelial system and thus help combat infection. Solution of pituitary also has a helpful effect not only on the uterus but also on other parts of the body. Of course, nursing at the breast should not be permitted. Large amounts of alcohol taken by mouth often prove helpful in cases of puerperal sepsis. Thus far no specific cure for puerperal sepsis has been found, but in many cases antistreptococcus serum is of distinct value, especially if it is used early in the disease.

TREATMENT OF CONDYLOMA ACUMINATA

To the Editor—A woman aged 25 married two years who has had no pregnancies and states that she never had gonorrhea developed multiple venereal warts about the vulva and anus about two years ago shortly before her marriage. A physician cauterized them with electrocoagulation and they returned more severely. Another well known surgeon removed them surgically some time later and within three months they again returned in still larger clusters so that when I first began treating her last November both the labia majora and minora and the entire perineum were covered with cauliflower verrucae. I have attempted to destroy them with caustics and succeeded in destroying some of them, but if an interval of two weeks elapses between treatments they return as bad as ever. Her general and past history is essentially negative. Routine laboratory work is negative. I would greatly appreciate any suggestion offered.

M D

ANSWER—Condyloma acuminata, or cauliflower verruca, is due primarily to a filtrable virus but secondarily is dependent in part on an irritating discharge. Before anything else is done the feces and the leukorrheal discharge should be examined for the presence of *Trichomonas intestinalis* and vaginalis. In quite a large number of these cases that is the real cause of the disease, and if it is removed the discharge disappears and the process clears up at once. There have been various preparations recommended for the treatment of *Trichomonas vaginalis* infestation. One that has recently been recommended is the use of a douche of phenol mercuric nitrate, 1 10,000, in water, the douches being used once or twice a day. If vaginal and intestinal parasites are not found to explain the trouble, the use of local cauterization of each single lesion in a painstaking manner with trichloroacetic acid is recommended. In doing this it is necessary to be careful not to get any of the acid on the glabrous skin. The best practice is to cut down the end of an applicator to a point and then apply a small drop of the trichloroacetic acid on each one of the verrucae. Another remedy that works quite well is the use of local application to each lesion of a 40 per cent solution of formaldehyde. Along with this the use of potassium permanganate sitz baths 1 4,000 twice a day will be found of great value. They will tend to keep the parts dry and free from irritation. In treating condyloma acuminata it is well to remember that, as long as a single lesion is left, the filtrable virus is still present and is a potential start of a fresh infestation.

PITUITARY INADEQUACY—FRÖHLICH TYPE

To the Editor—While doing a routine examination on a child 10 years of age I was impressed by his peculiar distribution of fat which is of the female type. He is 55 inches (140 cm) in height and weighs 111 pounds (50 Kg). His physical examination is essentially negative with the exception of the genitalia. The penis is of normal size. The scrotum is very small. The right testicle is present but infantile being about the size of a small bean. The left testicle is absent from the scrotum and cannot be felt in the canal. It is apparently in the abdomen or entirely absent. Is this a true Fröhlich syndrome? Will adolescence correct this condition? Would you advise anything therapeutically? Will this child be sterile? Kindly omit name.

M D Connecticut

ANSWER—This case is one that might be called a modified Fröhlich type of pituitary inadequacy, involving particularly the anterior lobe of the pituitary gland. It would be necessary, in order to add to the information at hand to have a roentgen examination of the skull made with a view of determining the size and character of the sella turcica, also a complete examination of the blood, including urea nitrogen, uric acid, creatinine, chlorides, carbon dioxide tension of the plasma, sugar and calcium, which would throw much light on the changes brought about by the deficient pituitary on other tissues of the body.

Adolescence in a few cases will bring about normality, but if one wants to determine such an eventuality and the result is

negative, much precious time will have been lost which probably cannot be regained. It is therefore advisable to treat the case at once.

The therapeutic agents are

1 Anterior lobe of the pituitary given hypodermically three or four times weekly in doses of 1 cc, beginning with one-half or one-third this dose at first. If there is no untoward reaction such as much local irritation, or much flushing with headache, the larger doses are to be given for two or three months with an interval of a few weeks' rest afterward, before beginning them again.

2 Thyroid medication in small doses, as low as 0.006 Gm. (one-tenth grain) daily unless rapidity of the pulse and other thyroid symptoms supervene.

3 Sodium iodide in saturated solution, a few minims daily, well diluted, during alternate weeks.

4 Anterior lobe of the pituitary gland (desiccated) in doses of from 0.2 to 0.3 Gm two or three times daily, midway between meals on a completely empty stomach. This is to be given in capsules. While there is much discussion at present as to whether this material is effective by mouth, it has been used with good effect.

The urine is to be examined regularly. Should kidney irritation manifest itself by the appearance of albumin and casts, all pituitary medication is to cease.

Later on, if the testicles remain small and undescended the anterior pituitary-like principle from the urine of pregnancy might be given in place of the ordinary anterior pituitary for a few weeks at a time, but usually the anterior pituitary alone is sufficient.

5 Carbohydrates and fats should be reduced to a minimum and the caloric intake reduced to about 1,000 calories three days a week.

The question as to the sterility of the child cannot be answered at present. The chances are that he will not be sterile. But within a year this probably can be determined by the development of the genital system. The best indicator of a successful treatment will be the rapid growth in height of the patient. This causes, among other things an attenuation of the body mass with a resultant diminution of the obese appearance. Also, a beginning pubic and axillary hair growth would indicate development.

WEIGHT REDUCTION

To the Editor—What would be the best method of weight reduction in a patient with the following history. A girl aged 14 years who is about 5 feet 7 inches (170 cm) tall and weighs 201 pounds (91 Kg) has always been large for her age and has always had an excessive appetite. Her parents are both large her father being 6 feet 2 inches (188 cm) and weighing almost 300 pounds (136 Kg) her mother weighing almost 200 pounds. This girl has had no past illnesses except the diseases of childhood and a right sided pyelitis. Investigation of the latter condition showed a very small, poorly functioning kidney on the right side with a kink in the ureter. There apparently is an endocrine dysfunction in this case and I have had the patient on anterior pituitary 2 grains (0.13 Gm) and desiccated thyroid, one-half grain (0.03 Gm) twice daily. The girl's menstrual function is normal. I watched her for two years and kept her on a limited diet at least a part of the time. This diet consisted of approximately 1,000 calories daily. Even when on this diet rather rigidly she lost but little weight. She is a school girl and is moderately active. Please omit name.

M D Iowa

ANSWER—The best method and indeed the only method of weight reduction in this patient, as in all patients regardless of endocrine disturbance, is to cause the energy intake in the form of food to be less than the energy output in the form of heat and physical work. When the energy expenditure of the patient, as determined by a basal metabolic test, is subnormal it is justifiable and advisable to administer a preparation such as desiccated thyroid in order to increase the energy consumption toward the normal. But even this does not insure a loss of weight unless the patient's food intake is insufficient to maintain the normal energy output. If the patient's basal metabolic rate is not below normal and thyroid is given to cause a loss of weight, it is obvious that the drug must be maintained indefinitely unless the patient reduces the food intake when the thyroid is discontinued. Thus in all cases the feeding habits of the patient are the crux of the situation.

It is apparent from the description that the patient, like her parents, has always eaten too much. It is also apparent that, whatever her protestations, she did not adhere to the diet prescribed. Success in her case must depend on the degree in which treatment is made a matter of vital interest and importance to herself so that she will follow prescriptions faithfully. At her age also, much may be gained by inducing her to take more physical exercise in the form of systematic physical training and games.

LYCOPodium IN BABY POWDERS

To the Editor—I am rather anxious to know whether lycopodium is a constituent of baby powders and whether to your knowledge it has a beneficial or harmful influence in its use as an external application and also whether or not any allergic reactions have been recorded from its use. Please omit name.

A L R

ANSWER—Lycopodium is the principal genus of the Lycopodiaceae, a family of the fern-allies. There are about 185 species, widely distributed in temperate and tropical climates. The commonest species *L. clavatum*, also known as staghorn moss, has spores, which constitute lycopodium powder.

This powder is used extensively in operating rooms for coating rubber gloves and tubes. It is also frequently used for covering excoriated areas such as the napkin area in infants, and it is sometimes mixed with talc. As such it may be a constituent of some baby powders. As a dusting powder it is probably beneficial although in the presence of open wounds its use is advised against because of the possibility of a resultant lycopodium granuloma, as reported by William Antopol (Lycopodium Granuloma *Arch Path* 16 326 [Sept] 1933).

M M Peshkin (Bronchial Asthma and Other Allergic Manifestations in Pharmacists, *THE JOURNAL*, June 7 1924 p 1854) reported the case of a student of pharmacy who developed coryza and bronchial asthma when lycopodium was inhaled and who gave a huge positive scratch test to lycopodium. Lambright and Albaugh (*J Allergy* 5 590 [Sept] 1934) reported three cases of lycopodium rhinitis one definitely proved in these cases the lycopodium was used in a powder for the hair.

The occurrence must be rare and positive tests to lycopodium are unusual.

Lycopodium is also extensively used in the preparation of fireworks.

TREATMENT OF SYPHILIS

To the Editor—A man aged 46 had a chancre May 30. Treatment with neoarsphenamine, 0.6 Gm. was started immediately. He received six injections and then arsenical treatment was stopped because of itching of the palms soles and extremities. He then received ten injections of iodohistmitol followed by two weeks of mercury inunctions. Then bismuth arspenamine sulphionate 0.2 Gm. was given intramuscularly once. Itching of the palms and soles recurred. I then gave him an injection of 0.1 Gm. of bismuth arspenamine sulphionate and again the itching recurred. It seems to me that this patient is extremely sensitive to the arsenicals. Kindly outline a plan of treatment leading to a clinical and serologic cure. The Wassermann and Kahn reactions are both 4 plus. Please omit name.

M D

ANSWER—The treatment this patient has received has been adequate. According to modern standards itching of the palms, soles and extremities is generally regarded as the danger signal of an impending arsenical reaction usually a dermatitis or hepatitis, and calls for a temporary suspension of arsenical treatment or a reduction in dosage. There is no way of avoiding or overcoming hypersensitivity to the arsenicals. It is impossible to outline a plan of treatment in such a situation that will lead to a clinical and serologic cure. Conservatism would suggest a course of one of the heavy metals preferably bismuth salicylate 0.2 Gm. intramuscularly for ten doses at five day intervals followed by a cautious resumption of neoarsphenamine in doses not to exceed from 0.3 to 0.45 Gm. for from six to eight injections. In early syphilis continuous or uninterrupted courses of treatment are advisable until the patient has had at least two or preferably three courses of alternate arsenical and heavy metal therapy irrespective of the outcome of the Wassermann and Kahn reactions.

DERMATITIS IN PACKING INDUSTRY

To the Editor—Last week I saw six cases of an acute dermatitis in the employees of a local meat packing house involving principally the skin between the fingers and the lower half of the forearm. This seems to be a new experience for these men who are old at the game but the condition has shown up since they have been working on cattle sent in from the drought section of the West which are being slaughtered for government use. I wondered whether you have had inquiries from other sections relative to the same disease and also whether you have any suggestions to offer as to what the condition might be other than an acute dermatitis of exogenous etiology. Please omit name.

M D Ohio.

ANSWER—There is an acute dermatitis which involves the hands and forearms of persons engaged in dressing slaughtered animals, which is not a rare condition. Certain individuals are more susceptible than others. Again those who develop acute dermatitis while dressing one species of animals may not be affected while dressing another species. Because of this fact some believe it to be the result of a sensitization to an animal substance contained in the intestinal tract acting as an

irritant. The disease is perhaps more frequent in the winter than in the summer months.

No scientific investigations have been conducted to determine the cause of this condition, therefore, but little of pathologic value is known. Among those engaged in dressing swine, it is known as "hog itch."

The inquiry states that acute dermatitis was seen in six men who were engaged in dressing slaughtered cattle. They were accustomed to doing this kind of work, yet the dermatitis was a new experience to them. This being the case, perhaps the acute dermatitis noticed in these cases is different from the one just mentioned.

PERNICIOUS ANEMIA AND CHOLECYSTITIS

To the Editor—A man of about 60 was run over by an automobile with resulting several fractures of the ribs and hemithorax. About ten days later a very severe attack of cholecystitis developed with perforation and localized abscesses. Operation was delayed for a week because of the fractures of the ribs and the poor general condition of the patient. Drainage of the abscesses and removal of the gallbladder were followed by a most remarkably smooth convalescence and there have been no residual abdominal symptoms. About six months later the patient presented himself with a severe pernicious anemia to which he has responded very rapidly with large doses of liver. Is there any connection between the trauma and the cholecystitis? Are the cholecystitis and the subsequent surgery responsible for the pernicious anemia? What available literature is there on the question of pernicious anemia following trauma? Please omit name and address.

M D New York.

ANSWER—While injury to the gallbladder may be followed by cholecystitis, it is of course not possible to say that there was any specific relationship in this case. It is extremely improbable that there was any etiologic connection between the cholecystitis and the pernicious anemia. Although there is a rather high incidence of gallbladder disease in pernicious anemia (Bethell, F H and Harrington, B D. The Incidence and Significance of Disease of the Gallbladder and Liver in Pernicious Anemia, *Am J Digest Dis & Nutrition* 1 256 [June] 1934), there is no evidence that it is a causative factor. Some types of liver damage (cirrhosis) may produce a blood picture somewhat similar to that found in pernicious anemia (Goldhamer, S M. Isaacs Raphael, and Sturgis, C. C. The Role of the Liver in Hematopoiesis, *Am J M Sc* 188 193 [Aug] 1934). The only type of "trauma" that has been reported as being followed by pernicious anemia is the surgical resection of the stomach or too great reduction in the intestinal length by anastomosis. This literature has been summarized by S M Goldhamer (The Pernicious Anemia Syndrome in Gastrectomized Patients *Surg Gynec & Obst* 57 257 [Aug] 1933).

STAINS ON TEETH

To the Editor—The upper central and lateral incisors of a girl aged 3½ years in excellent health have become decidedly black. The parents and curiously the child are much concerned about it. The only article of food she dislikes and rebels against is milk, otherwise she is on a general diet. A scholarly dentist who examined her maintains that nothing can be done to check this condition of a jet black discoloration. It occurs to me that the condition is evidence of an unbalanced diet or certain type of vitamin deficiency or some systemic aberration. Regardless of what the underlying factors may be the selective tendency for the upper teeth favors a local rather than a systemic etiology. If this is a vitamin deficiency how may this elective localization be explained? Your discussion of the etiology and method of procedure to combat this condition will be greatly appreciated. Please omit name.

M D New York.

ANSWER—In general, as Bunting says, "stains on teeth have no pathological significance other than they indicate a relative degree of malhygiene and give to the mouth an unsightly appearance." With respect to black stain or discoloration this is only partly true since a black stain may be found in mouths that have excellent care, and general discoloration of a tooth is frequently suggestive of death or advanced degeneration of the pulp. Little is known about the black stain that is superficial on the lateral surfaces of teeth or is close to the gum line, except that it is removed with ease and tends to recur promptly. Some of the black stains are of metallic origin, from deposits containing iron silver mercury or other metals. Deep discoloration of a whole tooth as a rule is caused by changes in the pulp. Mottled enamel is sometimes black but is not found in temporary teeth. Since the teeth involved in this case are temporary teeth that will be lost comparatively early no form of radical treatment is indicated unless frank pathologic changes can be demonstrated. The pulps should be tested for vitality. Roentgenographic examination may be made although it is unlikely that additional information will be gained in this way. Since vitamins diet and systemic dis

else have not been connected with this condition, the patient's limited consumption of milk and general health are not significant, and the treatment, in the absence of any further information as to the etiology of the discoloration, is confined to cleaning and polishing the visible surfaces of the discolored teeth

ACIDOGEN NITRATE

To the Editor—Can you give me any information regarding Acidogen Nitrate (Abbott)? This preparation is put up in capsules and about eight are given each day with meals to dilute its irritating action. The drug is supposed to diminish the body alkalinity (pH). Is the drug harmful? Has it any therapeutic value?

M D Jackson Mich

ANSWER—According to the catalogue of the Abbott Laboratories, Acidogen Nitrate appears to consist of 3 grains of carbamide nitrate (urea nitrate) per capsule.

Although the manufacturers propose the use of the preparation for 'adjunct therapy in various allergic conditions' hay fever, hyperesthetic rhinitis, urticaria, chronic urticaria, serum disease, allergic gastro intestinal affections (diarrhea) and asthma with productive cough, critical textbooks of pharmacology which have been examined do not refer to such use of urea or nitric acid. The claims do not do credit to a reputable pharmaceutical concern.

The ingestion of urea nitrate would be expected to yield an acid reaction. Nitric acid has been extolled by some physicians for the treatment of asthma and related conditions, but the treatment has never received general acceptance.

Acidogen Nitrate Capsules have not been accepted for inclusion in New and Nonofficial Remedies nor has the Abbott Laboratories requested the Council to consider the product.

CLAIMS FOR ANAYODIN

To the Editor—A circular letter from Ernst Bischoff Company on Anayodin contains the following statement: ANAYODIN comes nearest to being the ideal amebicide. It safely rids the intestinal tract of amebae usually with a single treatment of four pills three times a day for eight days. Does this statement express the present consensus of opinion? Is the product accepted by the Council?

M D Ohio

ANSWER—The statement is far too optimistic. There is no known amebicide that can be depended on to eradicate *Endamoeba histolytica* from the intestinal tract with a single course lasting eight days. Such propaganda is exceedingly unfortunate.

Anayodin is a proprietary name for chiniofon-N N R. The Council on Pharmacy and Chemistry has considered Anayodin and found it unacceptable for New and Nonofficial Remedies.

Chiniofon is recognized as one of the useful amebicides provided it is used in sufficient dosage over a sufficient length of time and the result is checked by repeated examinations of the stools. Frequently it is found advisable to employ alternating courses of chiniofon and other amebicidal drugs. Our correspondent is referred to the Query and Minor Note, 'Treatment of Amebiasis' THE JOURNAL, June 23, 1934 page 2134.

The Council has accepted the following brands of chiniofon: Chiniofon Searle and Chiniofon-Winthrop.

DOG DISTEMPER AND HUMAN PNEUMONIA

To the Editor—A client's sister developed pneumonia which terminated fatally while caring for some dogs in her kennels that were suffering from canine distemper. A specialist was called in consultation and he emphatically stated that the condition was due to an infection received from the dogs. From the description given and the veterinarian's diagnosis it is reasonable to believe that the dogs were infected with distemper complicated with the secondary organism of the pulmonary type (*Alcaligenes bronchisepticus-canis*). Can you give me any information or references that I may read on this subject? I realize that the information that I have given you is meager but it is all that was given to me. From personal observations I have reason to doubt that this condition is probable.

John H Rust DVM Wellesley Hills Mass

ANSWER—Dog distemper is caused by a filter-passing virus that is regarded as not pathogenic for man. *Bacillus bronchisepticus* may be associated with dog distemper as a secondary invader of the respiratory tract. This bacillus, also called *Alcaligenes bronchisepticus*, "has been found associated with infections of the respiratory tract in guinea-pigs, dogs and man" (Zinsser, Hans, and Bayne-Jones, Stanhope. A Textbook of Bacteriology, ed 7, New York, D Appleton-Century Company, 1934 p 650). Whether it can cause fatal pneumonia in man is not known. The best comprehensive article on dog distemper is by P P Laidlaw (A System of Bacteriology in Relation to Medicine, London, His Majesty's Stationery Office 7 232, 1930).

PHYSICAL QUALITIES OF FECES

To the Editor—Physiologists state that normal stools float. Can you tell me what the significance is of stools that habitually sink in water for years no matter what the diet is? What is the bacterial content of the stool? I have read somewhere that they compose two thirds of the bulk. Patients under my instruction have noticed the stools sometimes extruding bubbles of gas and sinking. Do you suppose that this is due to dissociation of gases caused by decrease in temperature or more probably that the fecal matter contains gases that are more readily dissociated than normal? I have noted that stools, particularly in patients with pernicious anemia have the property of sinking in water. These patients are supposed on account of the achylia to have an excess of putrefactive and other organisms according to Hurst throughout the intestinal tract. On this account the stools are more heavily laden with bacteria. Then again while the oxygen is almost absent in the large intestine it is present higher up in normal individuals but the erythrocytes in pernicious anemia patients are deficient in numbers and efficiency so that the interchange of gases is dislocated. These are questions that I have not seen discussed in the literature and I would appreciate it if you could elucidate some of these problems or tell me where I would be likely to find answers.

THOMAS I O DRAIN MD Philadelphia

ANSWER—No medical significance can be attached to the buoyant properties of stool.

The bacterial content of the stools averages one third of the dry weight.

Gases present in stools are formed as a result of bacterial action, fermentation and putrefaction. When gaseous stools are submerged, the gases will be released and bubble to the surface. The ease and rapidity with which this is accomplished depends on the adhesive qualities of the stool.

BRONCHIAL ASTHMA

To the Editor—I have an inquiry from a patient from New York City relative to this climate in his particular case. He writes me that he has a nonallergic bronchial asthma and wants to know whether the climate of northern Alabama would be more satisfactory than his present location over the next six months period. I would appreciate any information that you can give me in this connection. Please omit names if published.

M D Alabama

ANSWER—If it is true that the bronchial asthma is non-allergic a point that one should be certain of, the climate of northern Alabama, or for that matter any other southern region, will probably be quite satisfactory for the next six months period.

It is well known that the infectious type of bronchial asthma is often benefited by moving to a warmer climate where infections are less common and where there is more exposure to sunshine and fresh air. It is equally well known that persons with pollen asthma often do poorly when sent to southern regions where pollen is present most of the year.

IMPROVEMENT IN HEALTH AFTER EMOTIONAL UPSET

To the Editor—A woman who had been a chronic invalid for years having a chronic suppurative otitis media and repeated respiratory infections, which kept her in bed for weeks at a time suddenly had a great grief which inside of a week reduced her to death's door. The grief passed and she recovered. Since that time she has gradually become stronger and more resistant to disease. The chronic suppurative otitis media has ceased discharging and if she does get a cold or other infection she promptly throws it off and is gradually gaining in weight and feels good. Is there anything in the shock of grief that may cause this change in the human body? Please omit name.

M D., Ohio

ANSWER—There are many changes in body metabolism associated with emotion (Cannon. Bodily Changes in Hunger, Fear, Rage and Pain). It is possible that these might be a factor that could influence the bodily resistance to infections. However, one would hesitate to assert positively that this is true in this case. Other factors might be more important. For example, severity of emotional reaction in some instances is an indication of ambivalence in the cause for the emotion—something both feared and desired. In the absence of facts it is obviously impossible even to suggest that this might be true in this case but improvement in general health may well follow relief from conflicting emotions.

ISCHIORECTAL ABSCESS

To the Editor—Will you be kind enough to let me know what is the best medical or surgical treatment for an ischiorectal abscess of ten years duration?

JOSEPH DIAMONSTEIN MD Calumet City Ill

ANSWER—The treatment for ischiorectal abscess is surgical. The duration of the disease no doubt has made a great deal of fibrous tissue, which will delay healing.

The abscess should be opened widely and the fibrous tissue excised as widely as possible without interfering with the function of the rectum or anus. It should be packed wide.

open, including all the pockets or sinuses. The packing should be changed every few days so that the cavity will heal from the bottom. If there is an opening into the rectum below the sphincters or below the internal sphincter, it should be opened widely. If the opening is above the internal sphincter one should avoid cutting this sphincter until a second operation, if the sinus persists.

INSULIN AND NEURITIS

To the Editor—A woman aged 78 who has had diabetes for several years has been taking insulin 12 10 and 12 units of U 40 for the past fifteen months which has been sufficient to keep the urine sugar free on a sufficiently sustaining diet. She weighs 190 pounds (86 Kg). The pulse is 78 regular and normal. The systolic blood pressure is 130 diastolic 80. For the past nine months she has had neuritis in the right hand and forearm which has gradually become worse. The skin or surface temperature of the right hand and forearm is two or three degrees lower than that of the left but there has been no blanching or cyanosis. Roentgen examination shows no unusual sclerosis or arthritis. The blood picture is normal except that the blood sugar has been rather persistently elevated averaging around 200 or over. Six weeks ago an attempt was made to drive down the blood sugar by increasing the doses of insulin further control of diet, and dextrose intravenously controlled by insulin. The carbon dioxide has been consistently around 53, there is no acetone. Hot olive oil baths were used on the hand. There was slight improvement in the neuritis but this has not been progressive. Can you suggest any addition to the treatment or any other line of treatment? Please omit name.

M D Ohio

ANSWER—In a patient 78 years of age it is at times extremely difficult to decide whether pain such as described is due to neuritis, arteriosclerosis or a combination of the two. It is now pretty generally agreed that the elderly diabetic patient with arteriosclerosis does not always respond to insulin treatment as well as does the younger patient. It would seem wise, therefore, in the present instance to suggest that the patient be kept on a moderately high diet, well balanced, and that the insulin be omitted temporarily. Whereas this procedure would not be entirely accepted by all writers, it has been tried and has in certain hands given excellent clinical results.

DIURETICS—PROTEINS METABOLIZED AS SUGAR

To the Editor—Which of the purine base diuretics is most used and probably best in cardiac cases? What percentage of proteins are metabolized as sugar? Please omit name.

M D Pennsylvania

ANSWER—It is difficult to give a categorical answer to the first question. Caffeine is probably the most widely used purine base diuretic. However, theobromine sodium salicylate is also widely used and is generally regarded as more effective.

The percentage of protein metabolized as sugar, according to experimental data, lies between 46 and 58 per cent. The former figure is based on the work of Minkowski and von Mering on depancreatized dogs. The latter figure is based on the work of Lusk and his school on phlorhizinized dogs and has been generally accepted in this country as the basis for clinical calculations.

PELLAGRA OR ECZEMA

To the Editor—A woman, aged 28 who has been in excellent health all her life and is now in good health has eczematous patches on the inner aspect of both arms. She has had patches on the back of the legs in the groins and on the sides of the neck. These eruptions are always bilateral. I would call it pellagra but for the fact that she is in good health and full of pep. Is there any other disease except pellagra that has bilateral manifestations? If so what? Please omit name.

M D Mississippi

ANSWER—Most skin diseases of internal origin, as eczema, seborrheic dermatitis, lichen planus and psoriasis, to mention a few, are distributed symmetrically. The patches in the case mentioned are described as eczematous. Do they itch? If so, they may be patches of eczema. The distribution is typical for that disease but not for an ordinary case of pellagra.

BORN BLIND

To the Editor—In a person said to be "born blind" what is the posture of the eyelids—open or closed? And do the tear ducts function so that tears are shed? Please do not publish my name.

M D, Missouri

ANSWER—"Born blind" may mean any one of a dozen different things, and the position of the eyelids depends entirely on the condition that produces the lack of vision. In microphthalmus, for instance, the lids are closed, whereas in the atrophy of hydrocephalus the lids are open.

It is presumed that by "tear ducts" is meant "tear glands." If so they do function normally.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY *Written (Group B candidates)* The examination will be held in various cities throughout the country April 29. *Oral (Group A and Group B candidates)* New York, June 10. Sec. Dr. C. Guy Lane, 416 Marlborough St. Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY *Written (Group B candidates)* The examination will be held in various cities of the United States and Canada March 23. *Final oral and clinical examination (Group A and Group B candidates)* Atlantic City N. J. June 10-11. Group B application lists close Feb. 23 and Group A application lists close May 10. Sec. Dr. Paul Titus 1015 Highland Bldg. Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY Philadelphia, June 8 and New York, June 10. Application must be filed at least sixty days prior to date of examination. Sec. Dr. William H. Wilder, 122 S. Michigan Blvd. Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY New York, June 8. Sec. Dr. W. P. Wherry 1500 Medical Arts Bldg. Omaha.

CALIFORNIA Reciprocity San Francisco, Jan. 16. Regular Los Angeles, Feb. 4. Sec. Dr. Charles B. Pinkham 420 State Office Building Sacramento.

COLORADO Denver, Jan. 18. Sec. Dr. Wm. Whitridge Williams 422 State Office Bldg. Denver.

CONNECTICUT Basic Science New Haven, Feb. 9. Prerequisite to license examination. Address: State Board of Healing Arts 189½ Yale Station New Haven.

DISTRICT OF COLUMBIA Washington, Jan. 14-15. Sec. Commission on Licensure, Dr. W. C. Fowler 203 District Bldg. Washington.

ILLINOIS Chicago, Jan. 22-24. Superintendent of Registration, Department of Registration and Education Mr. Eugene R. Schwartz, Springfield.

MINNESOTA Minneapolis, Jan. 15-17. Sec. Dr. E. J. Engberg, 350 St. Peter St. St. Paul.

NATIONAL BOARD OF MEDICAL EXAMINERS *Parts I and II* The examinations will be held in medical centers where there are five or more candidates, Feb. 13-15. Ex. Sec. Mr. Everett S. Elwood 225 S. 15th St. Philadelphia.

NEVADA Reciprocity Feb. 4. Sec. Dr. Edward E. Hamer Carson City.

NEW YORK Albany, Buffalo, New York and Syracuse, Jan. 28-31. Chief Professional Examinations Bureau Mr. Herbert J. Hamilton, Room 315 Education Bldg. Albany.

SOUTH DAKOTA Pierre, Jan. 15-16. Dir. Division of Medical Licensure Dr. Park B. Jenkins Pierre.

VERMONT BURLINGTON, Feb. 13-15. Sec. Board of Medical Registration Dr. W. Scott Nay Underhill.

WASHINGTON Seattle, Jan. 14-16. Dir. Department of Licenses Mr. Harry C. Huse Olympia.

WYOMING Cheyenne, Feb. 4. Sec. Dr. W. H. Hassel Capitol Bldg., Cheyenne.

Tennessee June Examination

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held in Knoxville, Memphis and Nashville, June 14-15, 1934. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. One hundred and eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Stanford University School of Medicine	(1933)		1
Tulane University of Louisiana School of Medicine	(1934, 2)		2
Johns Hopkins University School of Medicine	(1931)		1
St. Louis University School of Medicine	(1934)		1
University of Rochester School of Medicine	(1933)		1
Meharry Medical College	(1932), (1934, 32)		33
University of Tennessee College of Medicine	(1934, 28)		28
Vanderbilt University School of Medicine	(1933) (1934, 40)		41

Seventeen physicians were licensed by endorsement from January 9 to August 30. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad of
College of Medical Evangelists	(1933)	California
Tulane University of Louisiana School of Medicine	(1926) N B M Ex.

Book Notices

Outline for Psychiatric Examinations. Edited by Clarence O Cheney M.D. Director New York State Psychiatric Institute and Hospital. Cloth Price \$1.50. Pp 134. Published by the New York State Department of Mental Hygiene Albany. Ullea State Hospitals Press 1934.

This is a revision of the Guides for History Taking and Clinical Examination of Psychiatric Cases edited in 1921 by Dr George H Kirby. Dr Cheney, the successor of Dr Kirby as director of the New York State Psychiatric Institute and Hospital, assisted in the preparation of the 1921 edition, which itself was modified from the original set of clinical guides devised by Dr Adolph Meyer some fifteen years previously for use in the New York State hospitals. In this revised work Dr Cheney has made a number of amplifications and alterations in keeping with the increased use to which the Guides has been put by medical students and psychiatrists in various fields of activity. The same division of material as in Kirby's edition is maintained, and, except for minor variations, that work has been kept relatively intact. There are sections on the psychiatric anamnesis, on special personality study, on physical and mental examinations, on body development and endocrine glands and on examination of uncooperative patients. Particular emphasis has been laid, in the section on family and personal history, on personality studies. A noteworthy addition is the chapter on the psychiatric examination of children and equally significant is the classification of psychiatric problems in children. The classification of mental disorders, which was approved by the American Psychiatric Association at its 1934 meeting with definitions and explanatory notes compiled by the editor, has been included. The book contains fifty pages more than the earlier work and will undoubtedly continue to serve as the best of its kind for the practical handling of the psychotic patient by both the intramural and the extramural psychiatrist.

Das Glaukcomproblem und die Glaukcomoperationen. Von Dr Leopold Müller Primaraugenarzt im Kaiserin Elisabethhospital in Wien. Boords Price 8 marks. Pp 103 with 1 illustration. Vienna Wilhelm Moudrich 1934.

The first six pages of this booklet, in which the author emphasizes the necessity of differentiating between true or primary glaucoma and secondary glaucoma, are of inestimable value. After that the remaining sixty-one pages of part I leave much to be desired. All true glaucomas are divided into JGLK comprising what is recognized as inflammatory or, better, uncompensated glaucoma, and G L K spl, which includes glaucoma simplex or compensated glaucoma and a combination of the two called KGLK. All other forms of glaucoma are relegated to the medieval trashbox. The author attributes JGLK to a congenital predisposition plus an excessive secretion from the ciliary gland (vide Duke Elder) and an excess in the LO (liquor ophthalmicus) of a mythical substance that he calls zylin, which is supposed to be somewhat akin to the principles of the posterior pituitary lobe. Closure of the

chamber angle is accounted for by an edema of the sclerotic fibers of the pectinate ligament, "which can never be proved." G L K spl, however, is due to excessive secretion from that selfsame ciliary gland but without any involvement of the controlling nerves, and consequently the physical action is different. The characteristic excavation of the nerve head is not due to pressure he concludes, but to a mysterious infiltration of the nerve head by liquor ophthalmicus, with consequent formation of Schinabel caverns and ectasia. Much emphasis is placed on some twenty-odd cases of G L K spl without hypertension that he has observed during his lifetime. Throughout these sixty-one pages are numerous statements emphasized by capitalizations. The majority of these do not agree with the modern concepts of glaucoma, and those who are familiar with the evidence shown by the painstaking experimental work of modern investigators will wonder at the temerity of the author. The second part of the book is devoted to the surgery of glaucoma and is confined to discussion of cyclodialysis, Müller's modification of the Elliot trephining operation, and the classic iridectomy. The medical treatment of glaucoma is dealt with in a rather summary fashion and in statements that are so positive that one is led to wonder whether or not a more benign form of glaucoma attends the Kaiserin Elisabethhospital than other hospitals abroad and in this country. However, several interesting statements appear. One is that cyclodialysis is so uniformly successful in controlling hypertension subsequent to cataract operation that in malignant G L K spl the lens should be extracted even though it is not cataractous, the operation to be followed later by a cyclodialysis. Hofrat Dozent Dr Leopold Müller has published some nice pieces of work, but this cannot be included among them.

A Textbook of Medical Diseases for Nurses Including Nursing Care. By Arthur A. Stierens A.M. M.D. Honorary Consulting Physician to Philadelphia General Hospital and Florence Anna Ambler B.S. R.N. Principal School of Nursing Samaritan Hospital Troy New York. Second edition. Cloth Price \$2.75. Pp 513 with 9 illustrations. Philadelphia & London W. B. Saunders Company 1934.

This book gives a brief but comprehensive outline of medical diseases and study for the graduate nurse. The volume is intended as a reference work. Each disease is defined, with the etiology, pathology, symptoms, complications, diagnosis and prognosis, together with an outline of treatment and nursing care. The authors state that their object in writing the book is, first, the education of the nurse in a potential knowledge of those diseases and processes with which she will have to deal and, second, training in actual nursing care of the patient, and the intelligent execution of the physician's orders. There are some valuable procedures outlined in the appendix which have been found satisfactory after trial in the Philadelphia General Hospital.

Outline of Clinical Psychoanalysis. By Otto Fenichel M.D. Translated by Bertram D. Lewin M.D. and Gregory Zilboorg M.D. Cloth Price \$5. Pp 492. New York Psychoanalytic Quarterly Press W. W. Norton & Company Inc. 1934.

In this book Fenichel has brought together the psychoanalytic concepts of the clinical varieties of neuroses and psychoses into a systematic treatise. It thus constitutes a systematic (and the first) textbook of clinical psychoanalytic psychopathology. The material has been collected from an enormous literature combined with the personal clinical experience of the author, the fundamental points of distinction between the different types are illustrated by brief statements of analytic interpretation of actual cases. The book undoubtedly will do much to crystallize the concepts of clinical psychoanalysis and to bring them into correlation with medical practice. It has great value for the practicing analyst and the student of psychoanalysis, rendering available conveniently the work of many authors. For an intelligent reading of the book, however, a general knowledge of the principles and theories of formal psychoanalysis is necessary. As Fenichel says in the introduction 'we must assume that our readers are acquainted with the methods of psychoanalysis as well as with the general theory of the neuroses.' Conceding this limitation, it is difficult to praise the book too highly. The work has been done excellently and even though he may not subscribe to the views expressed, the reader cannot fail to obtain a far better orien-

Medicolegal

Malpractice Fragments of Extracted Tooth Lodged in Lung—The plaintiff sued the defendant-dentist for malpractice, claiming that while extracting several of her teeth under a general anesthetic the dentist permitted fragments of one tooth to become lodged in her right lung, and that he failed to inform her of that fact. Judgment for \$25,000 was given for the plaintiff, and the defendant dentist appealed to the Supreme Court of Oregon.

The trial court did not err, said the Supreme Court in permitting an expert witness to testify that the treatment and care administered by the defendant, as outlined in a hypothetical question, was not in conformity with that degree of care, skill, diligence and knowledge ordinarily possessed and exercised by the average dentist in good standing in the same or similar localities. This testimony did not trespass on the province of the jury. The trial court erred further contended the defendant in instructing the jury that he was required to exercise the degree of care ordinarily exercised by a specialist, since there was no allegation in the complaint that he was employed by the plaintiff as a specialist. Regardless of the allegations of the complaint, said the Supreme Court, the defendant as a witness in his own behalf without objection placed himself in the category of a specialist. He testified that his main work was extracting teeth and he classified himself as an extraction specialist. If this was true, then the plaintiff was entitled to the defendant's skill as a specialist.

Two allegations in the complaint contended the defendant which charged that he 'hurriedly, carelessly, negligently and wantonly failed and neglected' to exercise care to see that no tooth or fragment thereof escaped into the trachea or so failed and neglected to discover whether any extracted tooth, or fragment thereof had not been removed from the plaintiff's mouth, should on his motion have been withdrawn from the consideration of the jury because there was no competent evidence to establish the negligence alleged. The Supreme Court held, however, that it was proper to allow the jury to consider the allegations. During the operation the plaintiff was unconscious. No one else was present except the defendant and his assistant. The plaintiff could not testify as to any of the alleged acts of negligence and obviously the others present would not. The fact remains, said the court, that fragments of a tooth were not removed from the plaintiff's mouth and that they escaped into the trachea. The jury could, in view of the circumstances and of the testimony of expert witnesses reasonably infer that the defendant's negligence as charged in the allegations was responsible therefor.

The Supreme Court could find no error in the record and consequently affirmed the judgment for the plaintiff—*Schamoni v Semler (Ore.)* 31 P (2d) 776.

Libel and Slander Report and Testimony of Examining Physician Privileged—Oakes sued the Weil Baking Company and Goldenberg its president, for damages for injuries attributed to a kick administered by Goldenberg. Prior to the trial, on the demand of the attorneys for the defendants in that suit, Oakes submitted to an examination by Dr Walther who in a written report to the attorneys stated, in part:

I consider the patient's mental state decidedly abnormal for a man of twenty-five; he is mentally undeveloped in my opinion.

At the trial, the report was read into evidence by Dr Walther. Subsequently Oakes brought the present suit against Dr Walther for libel and slander, alleging that the portion of the report quoted above was false and that Dr Walther knew of its falsity that it was made to humiliate and discredit him, and that it had no connection with the purpose for which he submitted himself for examination and was therefore entirely uncalled for. Judgment was given for the physician, and Oakes appealed to the Supreme Court of Louisiana.

A communication, said the Supreme Court, made in good faith, on any subject matter in which the party has an interest or in reference to which he has a duty, either legal, moral or social if made to a person having a corresponding interest

or duty, is qualifiedly privileged. And such a communication, even if untrue, if made as indicated and without malice, cannot be the basis of an action for libel or slander. Within the rule just announced, Dr Walther had a qualified privilege to make the statement of which the plaintiff complained. He had an interest in the subject matter about which he was writing. He had been employed to ascertain the plaintiff's physical condition and to communicate the result of his findings to his employers. He had become possessed of information affecting their rights, and it was clearly his duty to give them that information. It follows, therefore, that in making his report to his employers the defendant committed no actionable wrong, unless he acted maliciously, which the record shows was not the case. The defendant testified that his examination of the plaintiff, on which his report was predicated, was both objective and subjective. The plaintiff's claims as to his alleged injuries were apparently unsatisfactory to the defendant, and the statement of which complaint was made was clearly written, said the court, in explanation of the defendant's inability to understand the plaintiff's claims. This explanation, further observed the court, was obviously made in good faith for the purpose of showing why a subjective examination of the plaintiff was unsatisfactory and why the defendant reached the conclusion that there was little or no basis for the plaintiff's claim of extensive injury in his suit against the baking company and Goldenberg.

The testimony given by Dr Walther in court in the prior case in response to questions by counsel, was presumptively privileged and before this presumption can be overcome the court said the plaintiff must show affirmatively that the testimony was not pertinent and material to the issue involved in the case. This, the court said the plaintiff failed to do. The judgment of the trial court in favor of the physician-defendant was consequently affirmed—*Oakes v Walther (La.)* 154 So 26.

Insurer's Right to Autopsy—Cremation of Insured's Body—The defendant insurance company issued a policy providing indemnity against the accidental death of Schachner. The policy conferred on the insurance company "the right and opportunity to make an autopsy where it is not forbidden by law." Schachner died on January 3, from asphyxiation occasioned by breathing poisonous illuminating gas. In accordance with directions in his will his body was cremated. Later, on January 8, his widow, the beneficiary named in the policy, learned for the first time of the policy when a safety deposit box was opened. The insurance company refused to pay on the policy and the widow brought suit in the district court of the United States for the northern district of Illinois, eastern division. Judgment was given for the widow, and the insurance company appealed to the circuit court of appeals, seventh circuit.

The insurance company contended that the cremation of the body before it had an opportunity to make an autopsy relieved it of liability under the policy. Ordinarily, said the circuit court of appeals, under a policy similar to the instant one, if the insurance company was refused permission to make an autopsy it would be absolved from liability. But here the cremation was carried out before the widow had knowledge of the existence of the policy. There was no evidence that the cremation was not procured in good faith. There was no undue haste in disposing of the body. There was no obligation on the part of the widow to keep the body indefinitely on the possibility that at some future time an insurance policy granting the insurer the right to make an autopsy might be found. The beneficiary was under no duty to tender the body for autopsy. An autopsy may be required only on demand of the insurer seasonably made. If after death and before a request for an autopsy has been made, the circumstances have become such that the request would be unavailing, this of itself should not bar recovery on the policy. That there might be circumstances under which the insurer would not have the right to make an autopsy is clear from the clause of the policy which permits it where it is not forbidden by law. Where it is so forbidden, the claim must be disposed of as though no right to autopsy had been given. The parties to the policy must have contemplated that if, without fault of the beneficiary,

it was impossible to produce the body for autopsy, this of itself would not defeat recovery. If it were otherwise, the right of recovery under such a policy would be defeated if before it was possible to make an autopsy the body had been destroyed in a fire or blown to bits by an explosion, or rendered unavailable through any other of the many possible happenings. The court was satisfied that, under the circumstances of this case, cremation of the body before the insurance company had an opportunity to request an autopsy did not of itself bar recovery.

The trial court correctly charged the jury, said the circuit court of appeals, that if the evidence tended to show that the insured's death might have been either accidental or suicidal, and if the evidence did not preponderate to show suicide, a presumption arose that the death was accidental. There is an initial presumption against death by suicide. A coroner's verdict of accidental death was attached to the proofs of death delivered to the insurance company and as such was received in evidence. The trial court properly instructed the jury that the coroner's verdict constituted no evidence of the cause of death but was received in evidence merely to show compliance with the insurance policy which required proof of death to be delivered to the company. A coroner's verdict does not constitute evidence of any fact or finding therein stated and is not admissible as such.

The judgment in favor of the beneficiary was accordingly affirmed.—*Ocean Accident & Guarantee Corporation Limited, v. Schachner*, 70 F (2d) 28

Paternity of Baby Born 250 Days After Alleged Intercourse—The defendant was convicted of being the father of the complaining witness's illegitimate baby and appealed to the Supreme Court of North Dakota, contending that the evidence was insufficient to support the conviction.

The baby was born April 7, 1932. The complaining witness testified that the first act of intercourse between her and the defendant occurred during the first week of August 1931, approximately 250 days prior to the birth of the child. The period elapsing between the alleged intercourse and the birth of the child, observed the Supreme Court, was thirty days less than the normal gestation period, and in order to convict the defendant on the charge preferred against him, evidence was necessary to show that the birth was premature. No such evidence was produced, although the birth occurred in a hospital and was attended by a physician and nurses who could have been called as witnesses. In the absence of evidence showing a premature birth, a presumption arises that the birth occurred at maturity. Unless in this case the birth was premature, said the court, conception necessarily occurred before the date on which it is claimed that the defendant had intercourse with the complaining witness. Under such circumstances, the defendant could not be the father of the child. The Supreme Court therefore reversed the conviction and ordered a new trial.—*State v. Muldoon* (N D), 254 N W 475

Workmen's Compensation Acts Payment of Fees of Medical Witnesses Out of Attorney's Fee—The Oklahoma industrial commission allowed the claimant's attorney 20 per cent of the award as his fee, "providing said attorney pay the witness fee of the doctors who testified for the claimant at the hearing of this case." In vacating that part of the award enclosed in quotations, the Supreme Court of Oklahoma said that to permit the fees of the attorney to be divided with the physicians who testified in the case would produce a very bad situation. Two physicians testifying for the claimant estimated his disability at 75 per cent and 80 per cent total, respectively, while the physicians testifying for the employer placed the disability at not more than 10 per cent. Such divergence of estimates, observed the court, may be bona fide, but if the attorney fee which is based on the amount of recovery is to be divided with the doctors who testify in the case, there exists an incentive for a witness to aid in procuring a large award. In reaching this conclusion, the court referred to the case of *Illinois v. Prairie Oil & Gas Co*, 26 P (2d) 406 abstracted in THE JOURNAL, June 2, 1934 p 1878.—*Magnolia Petroleum Co v. Rader* (Okla.), 32 P (2d) 281

Annual Congress on Medical Education and Licensure Chicago, Feb. 18-19 Dr. William D. Cutter, 535 North Dearborn Street, Chicago, Secretary
Pacific Coast Surgical Association Santa Barbara Calif., Feb. 21-23 Dr. Edgar L. Gilcreest, 384 Post Street San Francisco Secretary

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Seventh Annual Meeting held in Chicago Nov. 2 and 3 1934

The President, Dr. W. S. MIDDLETON, Madison, Wis., in the Chair

Bone Marrow (Sternal) Biopsies

DR. E. L. TUOHY, Duluth, Minn. A review of the literature is made to bring out the widely varying technical methods and to determine whether hematologists feel that the circulating blood smear yields all that is needed, exclusive of bone marrow smears. Years of diverse interpretation of blood smears indicate that, once satisfactory marrow smears are available, much correlation is necessary to adjudge the cellular elements—their stages and degrees of maturation and preponderance. However, the blood work already done should relatively quickly point the way to the diagnostic and therapeutic criteria that the marrow shall provide in addition to circulating blood smear standards.

DISCUSSION

DR. F. J. HECK, Rochester, Minn. There is some difficulty in getting satisfactory staining of bone marrow preparations. Downey, following the suggestion of the Herrick Clinic at Panama, has obtained excellent results by using the Giemsa stain in twice the concentration ordinarily used.

Iron and Copper in Human Blood

DR. ADOLPH SACHS, Omaha. A large series of normal whole blood iron and copper determinations has been established in adult males and females. There is an apparent relationship between the copper and iron levels of human blood. When the iron content decreases, the copper content rises. This is nicely shown in a large series of cases including all types of anemia, pernicious, secondary and sickle cell, and leukemias. Tuberculosis and other diseases are included. In addition, comparisons of fetal and maternal bloods have been made, with some interesting observations. A blood copper deficiency, or, in other words, a copper anemia, has never been observed in the series.

DISCUSSION

DR. H. Z. GIFFIN, Rochester, Minn. Did Dr. Sachs make any observations on the use of copper in children?

DR. W. S. MIDDLETON, Madison, Wis. As far as our clinical experience in the adult is concerned, in no type of anemia in the wards of the Wisconsin General Hospital did we find that copper had any value. A series of eighty cases was studied and in none of these was copper effective.

DR. ADOLPH SACHS, Omaha. It was not felt that copper therapy was necessary, because at no time is there a copper deficiency in the human being. As to copper in children, it is a peculiar thing that right after birth the child instead of having a low copper content soon develops the normal amount. The series in children's blood is not large enough at present to report, but this will be done later.

Iron Retention Following Use of Ferric Ammonium Citrate in Hypochromic Anemia

DR. W. M. FOWLER and ADELAIDE P. BARER, PH.D., Iowa City. Iron balance studies have been done on over thirty patients with hypochromic anemia in an effort to determine the amount of iron retained as well as the factors that influence the retention of iron and hemoglobin regeneration. Six cases are reported in which only ferric ammonium citrate by mouth was administered. Two patients had anemia secondary to chronic uterine hemorrhage while the remaining four gave

no history of excessive blood loss. Large amounts of iron were retained by all patients, one retaining the equivalent of 676 Gm of metallic iron in forty-eight days and another 627 Gm in twenty-four days. The periods of maximum iron storage and of maximum hemoglobin regeneration coincide, although only a small percentage of the retained iron was utilized in hemoglobin formation. It was found, during the course of these balance studies, that patients with so-called idiopathic hypochromic anemia lost exceptionally large amounts of blood by menstruation. The average amount of blood lost by ten such patients was 258 cc, as contrasted to the average loss of 54 cc. in ten normal subjects.

DISCUSSION

DR. HOWARD L. ALT, Chicago. It is interesting that a woman can lose so much blood during menstruation without being conscious of it. This confirms the general impression that menstrual bleeding is an important factor in the cause of hypochromic anemia with achlorhydria. I have followed a series of such cases over a period of two years after the discontinuance of iron therapy. Three patients who had either a natural or an artificial menopause remained quite well, whereas it was the rule for the younger patients to have a relapse. Menstruation as a factor in the production of the anemia in these patients is thus suggested.

DR. CECIL STRIKER, Cincinnati. Did the feeding of hydrochloric acid expedite the storage of iron in the body?

DR. C. W. BALDRIDGE, Iowa City. In observing these results I have been impressed with the unreliability of the history in ascertaining whether or not a patient loses a normal amount of blood by menstruation. The patient's statement is only an opinion, because she usually has no standard with which to compare herself, the concentration of hemoglobin in menstrual fluid varies and commercial vaginal napkins are capable of absorbing a surprisingly large amount of fluid. By measuring the iron content of material lost by menstruation Dr. Barer found marked variations. Menstrual iron in one case was equivalent to only 7 cc. of the patient's own blood, while in another it was equal to 992 cc. These figures represent the extremes among those patients who considered that they menstruated a normal amount.

DR. W. M. FOWLER, Iowa City. I am unable to answer Dr. Striker's question in full. We have balance studies in progress to determine the influence of added hydrochloric acid and in those completed there has been no appreciable effect.

Splenectomy in Acute Erythroclastic and Thromboclastic Crises and in Hypoplastic Anemia

DRS. CHARLES A. DOAN, GEORGE M. CURTIS and BRUCE K. WISEMAN, Columbus, Ohio. The role of the spleen, both as an inhibitor and as a stimulatory factor, in the hemolytopoietic equilibrium has been demonstrated. Its influence in many clinical syndromes is reflected through a selective effect on one or more of the formed elements of the blood. Splenectomy, while recognized as an effective therapeutic measure in chronic congenital hemolytic jaundice and in certain types of thrombopenic purpura, has been considered to be definitely contraindicated in acute hemoclastic crises. Our studies of the dramatic cellular responses—including blood platelets, white cells and erythrocytes—that follow immediately on the removal of the pathologic spleen in patients with chronic disease, led to the conviction that, with adequate medical and surgical management, splenectomy should be a safe and rational procedure and the method of choice in the treatment of acute splenic crises, even in the presence of a severe anemia. Emergency splenectomy has therefore been performed during acute erythroclastic and thromboclastic crises and has been completely justified by the immediacy with which the pathologic process has been stopped and recovery initiated in critically ill patients. Blood transfusion and liver extract are distinctly contraindicated in hemolytic icterus, blood transfusions are indispensable in the treatment of thrombopenic purpura. The physiologic inhibitory and phagocytic functions of the spleen for blood cells underlie the rationale for the removal of the "normal" or atrophic spleen in hypoplastic anemia, with the reestablishment, at least temporarily, of a more normal equilibrium. Sixteen successful splenectomies covering a wide range

of diseases—hemolytic jaundice, thrombopenic purpura, Banti's syndrome, myeloid and lymphatic leukemia, polycythemia vera, and hypoplastic anemia—form the basis of the conclusions in this study.

DISCUSSION

DR. O. H. ROBERTSON, Chicago. I should like to know the authors' ideas concerning the mechanism of this striking rise in red blood cells following splenectomy.

DR. STANLEY E. DORST, Cincinnati. Did you make a second count after the spleen had been delivered but before the pedicle was cut and the spleen removed?

DR. M. A. BLANKENHORN, Cleveland. I should like to ask the authors what their diagnosis was when the chart showed an immediate postoperative leukocytosis of 70,000. Also I should like to ask them to reiterate the indications for the removal of a spleen weighing 40 Gm and how they came to the conclusion that such indications are valid.

DR. S. H. GOLDBAMER, Ann Arbor, Mich. I should like to know whether the counts were made on capillary or on venous blood, and whether there was a control on the blood volume in these counts.

DR. J. A. EVANS, La Crosse, Wis. The authors speak about liver extract being contraindicated in familial hemolytic jaundice. I understand that Murphy recommends liver extract. Would the authors tell us why they feel that liver extract is contraindicated?

DR. GEORGE M. CURTIS, Columbus, Ohio. Concerning the rationale of splenectomy in acute hemoclastic crises, my early studies showed an immediate postoperative rise in both red cells and hemoglobin. This ensued soon after the spleen was removed. Counts were taken fifteen minutes after splenectomy and thereafter at frequent intervals. These results of the immediate effects of splenectomy in hemolytic icterus raised the question of their occurrence in the acute crises. Since essentially an autotransfusion followed splenectomy for hemolytic icterus, it seemed to be indicated in acute hemoclastic crises. This has been accomplished twice, successfully. One patient with a large stone in the common duct had a double jaundice, an acute obstructive jaundice and a hemolytic jaundice. A cholecystostomy was made, and it precipitated an acute hemoclastic crisis. There was a fall in the hemoglobin and red cells. An emergency splenectomy was done fifty-eight hours after the cholecystostomy. The patient recovered from this, with a characteristic rise in red cells and hemoglobin. No such rise followed the cholecystostomy. Results give me hope that there can be surgical intervention in acute hemoclastic crises. This is largely contrary to the present view.

DR. BRUCE K. WISEMAN, Columbus, Ohio. During this study, some facts developed that seem to have an important bearing on the pathogenesis of congenital hemolytic icterus. The controversy has waged for many years as to whether the inherited defect is primarily an abnormality of the bone marrow or of the spleen. Those who adhere to the belief that the inherited defect is in the bone marrow regard the associated overactivity of the spleen in destroying red blood cells as simply a compensatory phenomenon designed to remove from the blood stream the defective units produced by an abnormal bone marrow. Those who regard the spleen as the tissue that has inherited the defect, in this case a defect resulting in an increased hemolytic activity, attribute the associated abnormality in the red blood cells as secondary to a damaged bone marrow produced by the long continued demand made on it for cells which it never can quite produce in adequate numbers without eventually some sacrifice in quality. If the first of these hypotheses is correct, no change in the quality of these cells as regards fragility, average diameter and thickness would logically be expected after splenectomy, since the primary defect responsible for the abnormal characteristics of these cells would still be intact. On the other hand, if the spleen is responsible for the damaged red cells incident to a hard-driven bone marrow, one would expect to find some cases in which the damage to the bone marrow had not progressed to an irreparable stage and which, on removal of the overactive spleen, might again become normal with the production of cells with normal physical characteristics. In one of our patients, a woman, aged 47, who had been the victim of her disease for at least twenty

years, the blood examined about eighteen months after splenectomy showed the presence of red blood cells without any of the defects so characteristic prior to the surgical treatment. In fact, in all our cases in which operation has been performed, the blood cells have shown a partial return to normal as regards fragility, diameter and thickness. Additional follow up of these cases will be made to see whether in any of the latter eventual restoration to normal will occur. In any case it would seem that the complete restoration to normal of the red cells in one case and the partial restoration in the others constitutes evidence that with the removal of the spleen the primary source of the inherited defect has also been removed, thus implicating the spleen and not the bone marrow as the primarily defective tissue that gives origin to the sequence of events terminating in the syndrome and characteristic features of congenital hemolytic icterus.

DR CHARLES A. DOAN, Columbus, Ohio. Dr Robertson asks as to the nature of the mechanism responsible for the promptness of the erythrocyte increase following splenectomy. We believe it to be of twofold origin. First in importance is the reservoir function of the spleen itself, greatly magnified when splenomegaly exists. Studies of splenic artery and vein blood at operation have indicated that in pathologic states, such as congenital hemolytic icterus, many more erythrocytes enter than leave this organ. Under the conditions of operative manipulation and the administration of epinephrine, sequestered red cells not already destroyed by the splenic phagocytes are forced into the general circulation and remain available after ligation of the pedicle. Secondly, the high reticulocyte percentage must reflect an unusually active bone marrow production of new erythrocytes which, with both reservoir and destructive activities of the spleen eliminated, accomplishes a more effective mobilization of essential blood elements as evidence, the immediate increase in erythrocyte fragility range postoperatively, followed later by a decrease. To answer the query as to just when the increase in circulating units occurs, we have made frequent observations on the day of operation before and during as well as after removal of the spleen. Some elevation in the total count from a well established base line may be noted before the patient is taken to the operating room and during the preliminary preparations, but the maximum peak is not attained until ligation of the pedicle has completely eliminated the spleen from the circulation. Dr Blankenhorn inquires as to the reason for a 70,000 total white count in case 6 of hemolytic jaundice immediately after splenectomy. The base line leukocyte counts in this particular individual had been between 12,000 and 15,000, reflecting a sensitive myelocytic marrow, which in response to the operative trauma gave an unusually generous transitory granulocytosis. All cells were mature actively motile elements with some nuclear "shift to the left," denoting an ordered delivery of new elements from the marrow. The variability in the degree and duration of postoperative leukocytoses in these cases has been no greater than that encountered following other types of surgical manipulation. To the request for the rationale of splenectomy in hypoplastic anemia in which no enlargement of the organ occurs I would cite the Frank-Krumbhaar law of increased erythrocyte resistance, erythremia, persistent thrombocytosis and leukocytosis following removal of the normal mammalian spleen. Our own experimental and clinical experience clearly implies a normal physiologic splenic control of blood destruction and inhibition of new cell delivery, which in the race of a waning competency on the part of the marrow may prematurely precipitate a critical shortage of essential units. Under such circumstances, when evidence of some regenerative activity remains the removal of a normal or even atrophic spleen may reestablish temporarily a positive balance, i. e., of more than two years' duration to date in the case reported in this series. The principles involved are not unlike those invoked in the advocacy of total removal of the normal thyroid gland for cardiac decompensation. Our studies have included both capillary and intravenous blood samples, in parallel with comparable observations throughout. Hematocrit and hemoglobin studies have confirmed the absolute increase in actual cell volume that follows splenectomy. Liver extract is not indicated in the treatment of congenital hemolytic jaundice because we believe the inherent difficulty to be in spleen

and not in bone marrow, the pathologic change in the marrow is a hyperplasia of erythropoietic tissue at the erythroblastic and not at the megaloblastic level. Liver extract is contra-indicated in hemolytic jaundice because in our experience and in the published experience of other investigators an exacerbation of the hemolytic diathesis frequently follows its use. No significant alteration in the reticulocyte percentage is apparent on the day of operation, though a prompt subsidence to normal occurs during the early postoperative convalescence. This may be interpreted to indicate that there is no sudden speeding up of the bone marrow delivery of new erythrocytes immediately after splenectomy to explain the relative erythremia that has been noted rather is the phenomenon that of decreased cellular destruction. May I reiterate that, while present knowledge of splenic function is incomplete, it is sufficient to justify ligation of the splenic artery or, when possible, the removal of the spleen, when evidences of acute cellular destruction or of critical marrow insufficiency point to this organ in clinical disease states.

The Intrinsic Factor (Castle) in Subacute Combined Cord Degeneration Without Anemia

DRS ROBERT T. PORTER and WALTER L. PALMER, Chicago. The secretory functions of the stomach in cases of subacute combined cord degeneration without anemia have received relatively little study. A patient with the history and evidences of subacute combined cord degeneration with a normal blood count and a histamine proved achylia was studied after the method of Castle. The patient's gastric juice obtained by histamine stimulation was incubated with ground beef and fed to two patients with typical pernicious anemia. There was no increase in reticulocytes or in the blood count after eleven days. This is interpreted as showing an absence of the intrinsic factor in this case.

DISCUSSION

DR. LOUIS LEITER, Chicago. I should like to ask whether controls were run on individuals who should have had the intrinsic factor.

DR. HARRY GOLDBLATT, Cleveland. I should like to ask why Castle's extract of normal gastric juice was not used as the control material in the second period. It would seem to me that this would have been better than to use liver extract in the second period.

DR. S. M. GOLDFRAMER, Ann Arbor, Mich. If the "intrinsic factor" of Castle is supposed to be a substance necessary for the maturation of red blood cells, why is there any hematopoiesis in this case, unless the 'intrinsic factor' is present in the gastric juice. Patients with pernicious anemia in relapse have red blood cell counts at different levels, some having two million, others three million, and so on. How can this variation be accounted for if the 'intrinsic factor' is absent? It seems to me that it is not a question of the absence of the 'factor' in the gastric juice but rather a quantitative deficiency that causes the variable degree of anemia. If this is true, in this case there is not a sufficient decrease in amount of the 'intrinsic factor' to produce the anemia at present, or the patient still has a sufficient amount stored in the liver to maintain a normal blood count. In patients with gastrectomy, the pernicious-like anemia may develop anywhere from two to fifteen years following the operation. Perhaps, if one waits long enough, this patient will develop an anemia.

DR. WALTER L. PALMER, Chicago. In some cases in which the entire stomach has been removed, pernicious anemia has failed to develop even after many years. Our feeling is that the relation between the intrinsic factor of Castle, pernicious anemia and combined cord degeneration is rather obscure in spite of the excellent work of Castle.

DR. ROBERT T. PORTER, Chicago. In answer to Dr. Leiter, we have studied two normal persons and found a definite reticulocyte response. In answer to the question why we did not use normal gastric juice in the second case, the patient became so concerned over the lack of improvement that we had to do something. As Castle has shown that ten days is sufficient time in which to secure response from this intrinsic factor, we concluded that it was from the liver extract. We had no chance to use the intrinsic factor of Castle in the first case because of the lack of cooperation of the patient. We

of course do not know much about the developing of red cells. Whether there is a factor in liver that is comparable to the combined extrinsic and intrinsic factors, I am unable to say.

Effect of Irradiation on White Blood Cells in Chronic Myelogenous Leukemia

DR F H BETHELL, Ann Arbor, Mich. With the decrease in number of all types of leukocytes after irradiation in chronic myelogenous leukemia (intensive study of six cases) there is a slight increase in the relative number of neutrophils, with a definite rise in the ratio of adult to young forms. The percentage incidence of cytoplasmic basophilic granulation is increased, and as the cells affected are chiefly young neutrophils this phenomenon may not properly be considered as degenerative in nature but rather as due to an effect on the cells before their release into the circulation. Vacuolization, however, occurs almost exclusively in the older cells and is probably a degenerative effect. The decreased percentage of vacuolated cells after treatment does not support the contention that the action of the roentgen ray on myeloid tissues is strictly degenerative.

DISCUSSION

DR CHARLES A DOAN, Columbus Ohio. I should like to ask, first, what dosage of x-rays was used in these cases. Second, what effect do the x-rays have on the agranular or very young forms, the myeloblasts, which predominate in some cases? Is it possible to administer a 'maturation dosage' of x-rays to these cells?

DR RAPHAEL ISAACS, Ann Arbor, Mich. This work shows for the first time that after roentgen treatment an increase is not found in the number of cells which, it is known are degenerated. The present view held by most people is that the x-rays kill the cells. Consequently we looked at the smears before and after roentgen treatment, and we found fewer killed cells after irradiation than before. The interesting thing is that no one has thought of looking at the blood before roentgen treatment to see the number of degenerated cells floating around. They looked after treatment and saw them apparently increased. Dr Bethell has found them decreased.

DR F H BETHELL, Ann Arbor, Mich. Our usual policy is to treat patients with myelogenous leukemia intensively over a short period rather than with smaller dosage over a longer period. The patients referred to in the paper received 200 roentgens, measured at the level of the skin, in each treatment. The areas treated were 16 by 16 cm. and were situated in the anterior and posterior splenic region. We have not recently treated patients in the myeloblastic stage, as in the few instances in which this has been done the results have been unsatisfactory.

Effect of Fever on the Circulation

DRS J MURRAY KINSMAN and JOHN WALKER MOORE, Louisville, Ky. Fever was produced by the use of a vaccine or an infra-red heat cabinet. With these fevers the cardiac output is increased when the pulse rate is below 120 but remains normal or actually becomes decreased when the pulse rate is above 120. The lesser circulation time is usually decreased with fever, but it seems to bear no constant relationship to the output or the pulse rate. The venous pressure in fever from vaccine therapy shows little or no change from normal, whereas it shows a decided rise with fever resulting from infra-red cabinet heat. The systolic and diastolic blood pressures are almost invariably lower than normal with fever from infra-red heat, but little or no change occurs with fever from the use of vaccine. The work of the heart with fever as calculated from the work formula of Starling shows an increase when the output is greatly increased and a decrease when the output shows little change. The determinations of cardiac output and so on were carried out with the dye injection (direct) method.

DISCUSSION

DR L N KATZ, Chicago. This communication corresponds with experiments on animals. However, caution should be used with regard to the method employed for determining cardiac output in man. The accuracy of this method of measuring cardiac output has been seriously questioned. Consequently until such time as this particular method is checked with the direct Fick principle involving puncture of the right

and left ventricle, one can consider the interpretation as being suggestive but not proved.

DR WALTER M SWINSON, Dayton, Ohio. These data coincide closely with clinical observations that I have made during the treatment of patients with artificial fever by physical methods. I have found that methods requiring a prolonged period of induction result in more serious demands on the cardiovascular system than those methods which induce fever rapidly. If the method elevates the fever level to 105 or 106 F within forty to fifty minutes, the patient tolerates the remaining five or six hours of therapeutic fever at that level much better than if it required two hours to raise the temperature to the desired level. The newer methods that have been devised for the artificial induction of fever provide the physiologist and the clinician with instrumentation for valuable studies of cardiovascular function. It is apparent to those who are engaged in work in this field that knowledge of the physiology of fever is exceedingly inadequate. The means are now at hand for extensive studies in this field.

DR JOHN WALKER MOORE, Louisville, Ky. In answering Dr Katz's criticism of our injection method for determining the cardiac output, I would say that we have checked with close agreement the method against the direct Fick in dogs and against direct measurement of flow in heart-lung preparation and various types of glassware experiments.

DR J MURRAY KINSMAN, Louisville, Ky. Dr Moore has answered Dr Katz's question at least partially, but I might emphasize that we began to put faith in this method only after we had done exhaustive experimentation from all angles on dogs and in glass-water experiments. In those experiments we were able to calculate the output of fluid within 5 per cent. There is no point in going into the accuracy any more in detail here except to say that it is our belief that rebreathing methods are of little value in cases of cardiac decompensation because of the changes in oxygen level. We believe that they will not give an accurate picture of what is going on. We realize that our method will not be accepted entirely until others have had a chance to use it and until, as Dr Katz said, it is checked by the direct puncture. Dr Striker asked about the effect on the myocardium. So far as we can tell, we have noticed no bad effects. The dye is not toxic in the quantity we use. As far as puncture is concerned, no harm has been seen to result from it. Dr Middleton wanted to know about the changes in pressure. We do not know any more about that than stated. It is just a matter of theory as to whether the procedure here discussed reflects the true pressure inside the body. We have not investigated the venous pressure in the vein in relation to capillary pressure.

Precordial Leads in Normal Persons and in Patients with Ventricular Hypertrophy

DRS F D JOHNSTON, C E KOSSMAN and F N WILSON, Ann Arbor, Mich. Using a method that records the potential variations of a single electrode, we took leads from six different points simultaneously with lead I in a series of thirty normal persons. Similar curves were taken in a series of patients with ventricular hypertrophy. In normal subjects the chief upstroke, which is analogous to the intrinsic deflection of direct leads, occurred about 0.02 second earlier on the right side of the precordium than on the left. In left ventricular hypertrophy this difference in the time of the chief upstrokes is usually greater than normal, in right ventricular hypertrophy it is usually less. The normal precordial electrocardiogram and that obtained in curves of ventricular hypertrophy also differ with respect to the absolute and relative amplitudes of the different QRS deflections on the two sides of the precordium.

DISCUSSION

DR L N KATZ, Chicago. I wonder whether some of the differences in the onset of the rise of QRS in the precordial curves over the right and left ventricles could not be explained either (1) by an abnormal position of the two ventricles in relation to these fixed points or (2) by an abnormal degree of approximation or separation between the anterior chest wall and the heart. These factors must be ruled out before the changes can be attributed to the altered sequence of stimulation of the two ventricles.

DR. F. N. WILSON, Ann Arbor, Mich. We adopted this method of leading because we found that in animals it yielded precordial curves that resembled the curves obtained by leading directly from the anterior surface of the heart more closely than the precordial curves obtained by other methods. When the hind leg is used as the indifferent point in dogs, there is a striking resemblance between the precordial and the direct curves in most of the experiments but not in all. Experience has shown that the resemblance is still more striking and is more consistently found when the present method is used. The statement that precordial leads yield curves similar to those that would be obtained by leading from the anterior surface of the exposed heart is based not on theoretical considerations but on what is actually found to be the case in animal experiments.

Influence of Position and Contact of the Heart on the Electrocardiogram

DRS. J. R. SMITH and W. B. KOUNTZ, St. Louis. There has been considerable discussion concerning the nature of the human electrocardiogram. Lewis, in a study on animals, expressed the view that the human leycardiogram is characterized by an upward deflection in lead 1 and a downward deflection in lead 3 and that the dextrocardiogram is downward in lead 1 and up in 3. Barker and others, by stimulating the human heart directly, have found the opposite to be true in each instance. It has been demonstrated that contact of the heart to the chest and contact of the heart in the chest may influence tremendously the electrocardiographic curves. As it is impossible to separate these two factors with the heart inside the chest, a different technic was devised in order to separate the influence of these two factors. A dog heart-lung preparation (Starling) was set up; the thorax of a cadaver, recently dead, was opened and the heart removed. The apex of the dog's heart was connected by means of an electrode to the human esophagus, with the preparation outside the thorax. The esophagus of the preparation could thus be connected to an electrode in any portion of the human thorax. The three standard electrocardiographic electrodes were attached to the wrists and left ankle of the cadaver in the usual fashion and electrocardiograms obtained. Such an arrangement caused the cardio-electrical impulses arising in the dog's heart to be reflected in the cardiograms using the three leads from the cadaver, though the heart-lung preparation was outside the body. It was found that the direction of extrasystole complexes could be changed by modifying the point of contact of the chest electrode to right or left of the spine on the posterior thoracic walls or to the right or left anterior thoracic walls. Extrasystoles were produced by directly stimulating the lateral walls of the ventricles of the heart preparation with an interrupted current. With the chest electrode in the left anterior part of the chest, extrasystole complexes from either ventricle gave curves similar to those of Barker obtained in man. Changing the chest electrode to the right posterior part of the chest, and producing extrasystoles in the same way, resulted in curves like those Lewis obtained in the dog. From this work it would appear that contact of the heart within the chest and the electrical resistance of tissues through which the cardio electric impulse passes are important factors in determining the type of curve a given extrasystole will produce.

DISCUSSION

DR. F. N. WILSON, Ann Arbor, Mich. I am particularly interested in the present study, although I would not venture to say exactly what it means without careful consideration of the details of the experiments. There are one or two comments I should like to make. A cadaver, considered as a conductor of electricity, is not exactly the same as the living body. My associates and I made that discovery when we attempted to study the distribution of electric currents in a cadaver some two or three days old. It was found that the dependent parts of the body contained most of the fluid, and it seemed probable that this altered the conductivity of these parts and was responsible for some of the anomalous results that we obtained. I should like to point out also that normally the heart is completely surrounded by a conducting medium. The electrical field which it generates must be altered more or less by any procedure that changes the resistance between any two points

of this field. When the heart is removed from the body it may continue to generate the same currents, but the distribution of these currents is necessarily greatly altered, and the potential variations that occur at any point on the heart's surface may bear no resemblance to those that occurred at the same point when the heart was in its natural position. Merely exposing the anterior surface of the heart must greatly alter its electrical field. In some instances the three standard leads are adequate to detect these alterations, in other cases they are not. When the three leads remain the same, it is not justifiable to say that the electrical field of the heart has not been changed, for only three points of this field have been investigated.

DR. L. N. KATZ, Chicago. This excellent study, taken in conjunction with the work by Eyster and that of the laboratory with which I am affiliated, raises the question whether the vector analysis introduced by Einthoven might be incorrect as used at present. For example, recent studies of ours have shown that insulation of the heart completely abolishes the electrocardiographic deflections. We have found that the posterior muscle mass and the diaphragm are the good electrical conductors and that the blood vessels and lungs are the poor conductors. In reality, our work suggests that the position of the heart in the chest in relation to the good and poor conductors is perhaps the most important factor that determines the contour of the electrocardiogram.

DR. W. B. KOUNTZ, St. Louis. The curves here presented are not considered to be normal electrocardiograms, but rather a cardio-electrical impulse directed through the cadaver in such a way as to give a normal appearing electrocardiogram. We believe with Dr. Wilson that a body which has been dead for some time is not a good medium for study with regard to the electrical conduction. We have tried to avoid this as much as possible by obtaining bodies soon after death. The question of the relationship of the electrical axis is interesting. As the electrodes are moved laterally, in some bodies 4 cm. from the midline, there are changes in the character of the normal complexes. These complexes take on the features described as left and right axis deviation. Within a close range on both sides of the median line the normal complexes are upright in all leads, but the extrasystoles are inverted. The results of these experiments appear to conflict with the Einthoven theory. It appears that other factors such as conduction of the electrical impulse through the tissues, may influence the electrocardiogram. These results, however, must not be too hastily assimilated until conditions of conduction resembling more closely those found in the living body have been studied.

SYMPOSIUM ON RELATIONSHIPS OF HYPOTHALAMUS AND HYPOPHYSIS

1 Somnolence Resulting from Lesions in the Hypothalamus

DR. S. W. RANSON, Chicago. Prolonged somnolence lasting for many days can be produced in cats and monkeys by lesions in the hypothalamus. After recovery from the somnolence the monkeys showed a remarkable decrease in emotional excitability. They became tame and tractable, although before the operation they were wild and exceedingly difficult to handle. An explanation of these observations will be attempted.

2 Relation of the Hypothalamohypophyseal System to Diabetes Insipidus

W. R. INGRAM, PH.D., and CHARLES FISHER, PH.D., Chicago. Permanent polyuria has been produced in twenty cats by placing small lesions so as to interrupt the tractus supra-opticohypophyseus. Lesions elsewhere in the hypothalamus in a large series of cats have not produced such effects.

3 Effect of Hypothalamic Lesions and Stimulation of the Autonomic Nervous System on Carbohydrate Metabolism

DR. LOYAL DAVIS, Chicago. Hyperglycemia and glycosuria are not produced by pancreatectomy in cats that have a lesion of the hypophysis produced by the Horsley-Clarke stereotaxic instrument. Bilateral hypothalamic lesions, symmetrically placed with the stereotaxic instrument may be followed by pancreatectomy without the development of hyperglycemia and

glycosuria. Such lesions must be situated in the tuber cinereum slightly rostralolateral to the mamillary bodies at the level of the ventromedial hypothalamic nucleus. Stimulation of the superior cervical sympathetic ganglion and the stellate ganglion in cats produces a marked hyperglycemia and glycosuria. These results are not obtained following section of the splanchnic nerves or bilateral, symmetrical lesions of the hypothalamus.

The Recognition of Myxedema

DR. H. D. KITCHEN, Winnipeg, Manit. The term myxedema implies a profound metabolic disturbance and conjures up a picture of an individual whose mental and physical processes are greatly slowed, with expressionless face, tropic changes evidenced by thin dry hair and coarse dry nails and exhibiting adiposity and a very marked intolerance to cold. One expects to find on examination a low blood pressure, slow pulse and a basal metabolic rate of minus 30 or lower. Women may give a history of sterility or amenorrhea. Such is the picture that most physicians visualize when thinking of a case of myxedema, and yet in spite of this definite clinical conception or perhaps because of it, many cases are overlooked. Diagnostically most practitioners are prone to be concerned primarily with the patient's most outstanding complaint and neglect often to see the patient as a whole. There are several reasons for this. In the first place the history may be misleading and the patient may not complain of undue fatigue because he may not remember feeling any different and may regard his condition as normal. Intolerance to cold may also be taken for granted and the wearing of additional clothing (such as a sweater) in a comfortably heated room or extra clothing when outdoors and the use of extra bedding may have become so fixed a part of the routine that it does not cause any voluntary mention by the patient. A careful history, however, will usually elicit these facts which are of the greatest importance. Undue reliance on the basal metabolic rate and not enough on clinical evidence may prove fallacious, and there is unfortunately a tendency to demand that, in a case in which the suspicions are aroused, the basal rate must of necessity conform to the low level usually expected before the diagnosis of myxedema can be made. The greatest cause for error is undoubtedly the focusing of the attention on symptoms. These may be very pronounced and at times very misleading, because they do not suggest the underlying endocrine disorder. Anemia, joint pains, flatulent dyspepsia, menorrhagia, extreme dyspnea, and chest pain of anginal character are some of the common symptoms of myxedematous patients. This presentation emphasizes some of the difficulties that result from undue concentration on symptoms. Diagnostic errors of this sort can be minimized if patients are regarded not as stomachs, hearts or chests but as individuals.

Lipoid Pneumonia in an Adult

DR. FRED E. BALL, Chicago. In a case of lipoid pneumonia in an adult the cause was the long continued use of liquid petrolatum as a nasal spray. [The clinical history, pathologic changes and microscopic sections of the lungs were presented and the pertinent literature was reviewed.]

DISCUSSION

DR. J. J. SINGER, St. Louis. My experience with iodized poppy seed oil proves that vegetable oils do not produce the evil results that liquid petrolatum does. I have used iodized poppy seed oil in patients over a period of years and in children who have been much weakened and yet there were no signs of lipoid pneumonia. It is my experience that, since these children who are bottle fed and fall asleep with the bottle in the mouth are relaxed, a certain amount of milk enters the lung. One thing is certain, though it is sometimes forgotten, the cough reflex is not very sensitive in many people and objects that are swallowed apparently do enter the lungs. I am sure from the reports of a large number of cases recorded in children that many more cases have occurred than has been suspected. I mention the question of iodized poppy seed oil because it is brought up often by people who are not familiar with its diagnostic value and who believe that such occurrences happen. In my experience I have not had it happen. I find by the use of the various iodized oils that I am able to make a diagnosis that could not otherwise be made. By removing the fear that it is dangerous, papers of this sort will have a tremendous value.

Artificial Pneumothorax in the Treatment of Acute Lobar Pneumonia

DR. L. E. HINES, Chicago. Twelve selected patients with acute unilateral lobar pneumonia were treated by artificial pneumothorax. Nine received immediate symptomatic relief of pain and dyspnea. It appeared that the procedure brought on an artificial crisis in four patients. Four (33 per cent) died and necropsies revealed an early pneumonia in the opposite lung of two patients. A localized pyopneumothorax was present at necropsy near the site of thoracentesis in one patient.

Renal Status and Alkalosis

DRS. M. W. BINGER and E. H. BERGER, Rochester, Minn. A series of eight cases of renal insufficiency associated with alkalosis were studied. Six of the patients had duodenal ulcer, one a malignant ulcer of the stomach, and one had been treated for ulcer but no ulcer was found. All patients had received intensive alkali therapy. While data were lacking regarding the renal status prior to alkali therapy, it is probable that these cases presented some degree of renal damage prior to alkali therapy which impaired the acid base regulating function of the kidneys and concurrently the alkalosis augmented the renal insufficiency. It is emphasized that previously impaired renal function is an important etiologic factor in alkalosis and should be considered in the alkali treatment of peptic ulcer. It is noted that patients who have renal damage do not tolerate well either acid or basic salts, there being a tendency to develop acidosis when acid salts are given and alkalosis when alkalis are administered. The role that the liver plays in this balance is not definitely determined. In these cases there was little evidence of hepatic insufficiency.

DISCUSSION

DR. WALTER L. PALMER, Chicago. How long after the use of alkali therapy was the renal function determined? Also, in how many instances of previously determined impaired renal function did alkalosis develop? I have not observed any greater tendency to alkalosis in cases of impaired renal function than in those with apparently normal function. In my experience, when one follows the urea clearance test of renal function during alkalosis, the renal function decreases as the carbon dioxide increases. For instance, a patient with normal kidney function to start with will develop alkalosis. With the discontinuance of alkalosis the renal function has in my cases returned to normal except in a very few cases in which there was reason to think that previously existing renal damage had been present.

DR. WILBER E. POST, Chicago. The treatment of ulcer is out of my present line of study but I have had occasion to observe cases of alkalosis in connection with study of mineral metabolism over a period of several years in association with Dr. Hoffman and Dr. Thomas. It is well recognized that alkalosis is much more likely to take place in cases of obstruction of the pylorus. In fact, one can predict it with certainty if one gives a considerable quantity of alkali. In the next place, when a small amount of fluid is given with the alkali, alkalosis is likely to occur. A part of the significance of the latter is made clear when one recognizes in the studies of Dr. Hoffman that were presented to this society a year ago that the retention of water is equivalent to 1 liter for each 35 Gm. of sodium. If the patients do not get water the sodium will not be excreted and they will get alkalosis. In view of these observations, the part that appeals to me is this: it is a question in my mind whether renal dysfunction referred to in this paper is not in truth an impairment of the other tissues of the body. There is profound disturbance of water balance in the tissues, even to the point at which dextrose and salt solution injected subcutaneously will not be absorbed at all. The administration of acid and large quantities of water is, of course, the means of correction.

DR. NORMAN M. KEITH, Rochester, Minn. This work should remind one of the physiologic fact that the normal kidney is an important regulator of the acid base equilibrium of the body. The normal kidney is well able to excrete a large amount of acid or alkali. On the other hand, the damaged kidney is much more limited in its excretion of acid and alkali. For example, acid salts in glomerular nephritis can cause more marked acidosis than in the normal, and alkalosis in the cases

of Drs Binger and Berger occurred more often in cases showing previously damaged kidneys. Chronic nephritis is frequently latent and not diagnosed. Last June a patient of mine had a serious gastro-intestinal hemorrhage from a duodenal ulcer. The blood urea was found to be elevated to 90 mg per hundred cubic centimeters. He made a quick recovery from the hemorrhage, but the blood urea has never returned to the normal level and at present it is 60 mg. I have since investigated this case more thoroughly and have found that he undoubtedly has had a chronic renal lesion for at least ten years and that the gastro-intestinal upset caused an acute exacerbation.

DR. M. W. BINGER, Rochester, Minn. Answering the first question, one has to take into consideration that there are no two cases quite alike and so there are no two renal conditions quite on the same basis. I do not think any two of these cases reacted the same to the treatment for alkalosis. For instance, one patient with a diagnosis of duodenal ulcer came in practically in coma, in fact, we thought it was a primary renal disease. However, there were symptoms of alkalosis and this man on getting plenty of fluids—he was taking from 6 to 7 quarts a day—was an entirely different man, the symptoms of alkalosis entirely cleared up, and the blood urea fell from 146 to normal in a few days. In a second case, of arteriosclerotic hypertension in a man, it was about two weeks before the symptoms of alkalosis cleared up and the renal function improved. I think that would answer the second suggestion, that the results of treatment of alkalosis depend greatly on the urinary output and the renal function. It is not known what happens to the kidneys in this condition, whether there is a swelling of the kidney, whether it is an intrinsic chemical change, or whether it is a derangement of some specific function of the kidney, for example, the acid-base regulating mechanism. It is known that if plenty of fluid can be given, either by mouth or intravenously, the alkalosis per se will clear up in very short order. If there is damage to the kidney, the situation is entirely different. A similar condition is seen in nephritis, in which neither acid nor basic salts are tolerated well. One has to be very careful about subjecting such kidneys to abuse.

A True Enterorenal Syndrome

DRS E. G. WAKEFIELD and J. ARNOLD BARGEN, Rochester, Minn. From time to time we have observed patients who came to the hospital with abdominal cramps and marked distention, suppression of urine, cramps in the arms and legs, elevated blood urea, and normal carbon dioxide combining power and chlorides of the blood. For practical purposes it is necessary to consider these patients as cases of intestinal obstruction. It is not until after blood chemistry and urinary output are observed that one suspects the true nature of the condition. After administration of intravenous fluids, these patients begin to pass urine with a normal specific gravity, albumin about grade 1 (on a basis of 4) and an occasional red blood cell in the sediment. Synchronous with administration of intravenous fluids and application of hot abdominal stupes and warm rectal irrigations, the azotemia clears up and abdominal symptoms, even when marked, subside. The practical application and importance of differentiating these cases from true intestinal obstruction is apparent.

Absorption and Excretion of Calcium and Phosphorus in a Patient with a Colostomy and Ileostomy

DR. RICHARD M. JOHNSON, Minneapolis. An unusual opportunity for studying the fate of calcium and phosphorus in the intestine was afforded by a patient with a high colostomy and low ileostomy. Increased calcium intake was followed by a marked increase in ileac calcium elimination and a slight increase in urinary calcium excretion but failed to alter the phosphorus excretion appreciably. The administration of viosterol increased the urinary calcium and phosphorus excretion and decreased the ileac phosphorus elimination and slightly increased the ileac calcium elimination. Injection of parathyroid extract decreased the ileac elimination of calcium and phosphorus and greatly increased the urinary calcium and phosphorus excretion. In this one case the colon failed to excrete calcium or phosphorus at any time during the study. The reaction of the ileac content was acid the pH varying from 4.3 to 6.8. The acidity was greater during the fasting state

than after the ingestion of food. The reaction of the contents of the small intestine may possibly influence the excretion of calcium into the intestine.

DISCUSSION

DR. EDMUND ANDREWS, Chicago. I have made a series of estimations of the calcium in the fluid excreted by the lower part of the colon. Some of these have been on material passing by rectum and others on the reflux from double-barreled colostomies of the sigmoid. In some cases there was a carcinoma in the sigmoid from which the fluid came and in others it was normal. While I have never investigated the effect of viosterol on calcium administration, I have always been astonished at the insignificant amounts of calcium that were found in this fluid which does not seem to fit in well with the current concept of calcium excretion.

Abnormal Dextrose Tolerance Curves Occurring in Toxemia

DRS SAMUEL SOSKIN, M. DAVID ALLWEISS and I. ARTHUR MIRSKY, Chicago. The abnormal dextrose tolerance curves occurring in toxemic conditions have been generally interpreted as indicating an impairment of pancreatic endocrine function and consequent disability in the storage and oxidation of carbohydrates. We have recently demonstrated that the liver and not the pancreas is essential for the normal dextrose tolerance curve. The present report offers experimental evidence that toxins do not exert their effects through the pancreas but interfere with the homeostatic activity of the liver. [The bearing of these results on the interpretation of the dextrose tolerance curve in toxemic conditions, as applied to prognosis and carbohydrate therapy, was discussed.]

Effect of Oil of Peppermint in Emptying Time of Stomach

DRS H. I. SAPOZNIK, R. A. ARENS, HEINRICH NECHELES and JACOB MEYER, Chicago. We have been studying the effects of oil of peppermint on gastric secretion and motility in man and dog. The present report deals with the effect of oil of peppermint on the emptying time of the stomach as determined by roentgen examination with a barium milk meal. The normal emptying time of the stomach of six normal women was first determined by the barium milk meal and the average time was found to be 240 minutes. In one patient with gastroparesis, emptying time was 310 minutes. Following the admixture of 2 cc of peppermint oil to the barium milk meal there was a decrease in emptying time, the average time being 145 minutes, an average decrease of 45 per cent. Immediately after the peppermint barium mixture was taken, antiperistalsis was observed. This lasted for about fifteen minutes. It was our impression that the dose of peppermint oil (2 cc.) was too strong and may have been the cause of the initial antiperistalsis. We therefore determined the effect of peppermint lozenges on the reduction of emptying time by 38 per cent was noted. Contrasts with olive oil and chocolate candy showed a decrease in emptying time of 10 and 13 per cent respectively. When 100 cc of 7 per cent alcohol was added to the barium milk mixture the decrease in emptying time was 19 per cent. When 2 cc of peppermint oil was added to the alcohol the emptying time was reduced to 135 minutes, a decrease of 44 per cent. The results obtained may offer an explanation for the symptomatic relief following the use of peppermint oil in various gastro-intestinal disorders and the feeling of comfort obtained by use of camomile or creme de menthe after a heavy meal. Further studies on the effect of peppermint oil on the motility of the gallbladder and intestine are being continued.

DISCUSSION

DR. HEINRICH NECHELES, Chicago. In all probability, the action of oil of peppermint on the empty stomach is different from that on the meal-containing stomach. When oil of peppermint was added to a meal, the emptying time of the stomach was definitely decreased. I should like to add the observation of our roentgenologist that oil of peppermint greatly facilitates fluoroscopy of the duodenum, particularly in ulcer patients with pylorospasm, by relieving the spasm so that the duodenal cavity may be visualized immediately.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Benign Neoplasms of the Rat's Breast—Heiman carried out experiments to establish, if possible, the transplantability of benign neoplasms of the rat's breast, their rate of growth and their relation to malignant changes, and to determine the conditions for the assumption of the characteristics of malignant tumors. He found that benign fibromas and fibro-adenomas of the rat's breast are easily and continuously transplantable. They grow not only in the region of the mammary glands when transplanted but also in the axilla, groin, nape of the neck, outer side of the thigh and in the abdominal cavity. The transplanted tumors do not always retain the structure of the spontaneous tumors from which they are derived. The transplantability of a tumor is not a criterion of malignant manifestation. Although the growth energy of the tumors fluctuates widely, there has been no cessation in one series for fifty-three generations, in a second for thirty-three generations, in a third for thirty-two generations and in a fourth for sixteen generations, during a period of ten years. This type of tumor grows as readily in adult rats as it does in young rats. In the former the growth tends to glandular hyperplasia, in the latter to a

marked increase of fibroblasts. It has been found that three of the six primary fibro-adenomas of the breast which were transplanted through four generations or more became actively growing cellular tumors with the morphology of sarcomas. Some of the tumors ulcerate through the skin, but this is due only to pressure on the skin and is not an evidence of malignant change. With a large number of inoculations and the implantation of two or more fragments 3 mm in diameter, these benign tumors are readily transplantable for many generations in suitable hosts. The benign tumors as they developed into sarcomas required smaller and fewer fragments for transplantation. Krebziel has transplanted one such tumor (308) by the trocar method, using 3 mg of tumor substance, for fifty-six generations. Of sixteen rats with spontaneous benign tumors, six yielded tumors transplantable for from four to fifty-three generations.

Carbohydrate Tolerance in Cancer Patients—Taylor and Jackson undertook an investigation to determine further the incidence of a lowered carbohydrate metabolism in cancer and to study the relationship, if any, of the blood calcium to the carbohydrate tolerance in cancer patients. Thirty-five patients suffering from various forms of carcinoma were studied. There seems to be no direct relationship between a decreased sugar tolerance and cancer alone. There is some evidence that the decreased tolerance for carbohydrate encountered in about one third of the patients studied was due in part to the general malnutrition and cachexia commonly found in cancer. Some patients with a lowered sugar tolerance had definite involvement of the gastro-intestinal tract. Even in those patients in whom a lowered sugar tolerance was found, as determined by the usual criteria, it was not certain that such decreased tolerance curves were not due to delayed utilization of dextrose caused by the large amount of this material ingested. Most of the abnormalities found were consistent with the types found following the feeding of carbohydrate in nondiabetic patients suffering from starvation or malnutrition. The lack of direct relationship between cancer and sugar tolerance was shown still further by a consideration of the effect of roentgen radiation. Roentgen radiation did not produce any marked changes in the carbohydrate metabolism. When the tolerance for dextrose was normal at the outset, more than half of the patients studied showed an unchanged sugar tolerance following roentgen treatment. Of those patients who did show a change, the same number showed a trend toward normal as showed a further decrease in tolerance for dextrose. There was, however, a tendency among patients originally possessing a lowered tolerance for dextrose for the tolerance curves to become more normal. It was found impossible to predict from an analysis of initial sugar tolerance curves whether the outcome would be favorable or unfavorable. In patients who originally showed a normal tolerance for carbohydrate, the development of a progressively decreasing tolerance strongly indicated an unfavorable prognosis. It has been found impossible to show any relationship between the decreased sugar tolerance found in some cases of cancer and the total serum calcium.

Multiple Tumors in Tared and Irradiated Mice—Reinhard and his associates state that there is no evidence that short wavelength radiation changes the susceptibility of mice to the production of tar tumors, nor does the radiation alter the carcinogenic power of the tar used. They believe that the low spontaneous tumor incidence of the nonirradiated mice is a direct result of the tarring. In their irradiated group this low incidence may be attributed to the tarring also, or it may be a result of the radiation or a combination of the two. It is possible that the occurrence of the spontaneous tumors has merely been retarded, and, had the mice lived longer, a proportion of mammary carcinoma might have been obtained that would more nearly approximate the normal expectancy. The appearance of the multiple tumors, distant in all cases from the site of painting, may be considered evidence in favor of a general action of the tar. This is especially emphasized by the striking absence of tumors at the site of painting. However, the possibility of chance contact must not be overlooked but in view of the failure to produce tumors at the site of painting itself this possibility is somewhat remote. The authors call

attention to the difference in the histologic picture as between the multiple sebaceous adenomas produced in their series and the typical tar cancer produced locally by repeated paintings with this agent

Irradiation in Treatment of Cancer of Cervix—Taussig reports twenty-six cases of cancer of the cervix in which the treatment consisted of irradiation of the cervix and surrounding tissues and the surgical removal as far as feasible of the tributary pelvic lymph nodes. Eighteen fell into group 2 and eight into group 3 according to the degree of malignancy. In the selection of suitable cases he gives preference to younger persons in good physical condition, excluding all markedly obese patients and those with heart or kidney complications. Radiosensitive tumors with a high malignant index were also less frequently subjected to this procedure. The immediate operative result was usually satisfactory. There was rarely any postoperative shock except in the more advanced cases. The outlook is encouraging in the group 2 cases but discouraging in the group 3 cases. Of the latter only one patient has survived two and one-half years since operation. Of the group 2 patients, one died after operation, five died of recurrence from twelve to twenty-one months after operation, twelve are living, one with a probable recurrence, and eleven are clinically well for periods ranging from four months to three and one-half years. The operation is as follows: A midline incision is made under spinal anesthesia. After simple ligation and removal of the right adnexa, the posterior sheath of the broad ligament on that side is caught with a clamp and the ligament is opened, exposing the ureter. The iliac gland, the most common site of cancer metastasis is caught and ligated. When this gland and its surrounding fat are removed, the obturator nerve can be seen shining white and running straight toward the obturator foramen. After passing the finger between it and the external iliac vessels one can usually feel an elongated, usually rather round and firm, gland lying halfway between the iliac bifurcation and the femoral ring. By retracting the round ligament, one exposes this region and the removal of this obturator gland is effected without difficulty. If the parametrium is not thickened too much it is possible to follow the ureter down to where it crosses the uterine artery. At this point a definite round nodule or pair of nodules, the uterine glands or glands of Championnier can be felt. The removal of these glands is more difficult, since injury to the ureter must be avoided. It is often necessary to ligate the uterine vessels to accomplish this. In such instances radon seeds were

implanted into the lymph node. Two gold radon seeds of 15 millicuries each are implanted with a trocar along the course of the sacro-uterine ligaments. A third radon seed of equal strength is implanted into the loose connective tissue of the iliac bifurcation. In order to prevent the formation of a hematoma in the broad ligament, the connective tissue space that has been opened is compressed by suturing the round and sacro-uterine ligaments to one another at a distance of 4 or 5 cm. from their uterine insertion. The remaining wound is closed by a running peritoneal stitch. The same procedure is done on the other side. The abdomen is closed without drainage. This was usually followed by an intracervical application of radium.

Influence of Pregnancy on Tumor Growth—Emge correlates the clinical with experimental observations and concludes that 1 The influence of pregnancy on the behavior of neoplastic tissue depends on a complex set of factors 2 The growth rate of neoplasms is inherent, but the controlling mechanism is still unknown. Clinical evidence suggests that pregnancy favors a protective mechanism against tumor growth. 3 Neoplastic tissue takes part in the local and remote reactions incident to pregnancy, the ultimate result depending on the length of the gestational period. These changes are of a temporary nature. The extent of involution of benign neoplasms depends on their relation to the generative organs, particularly the uterus. 4 Neoplastic tissue sensitive to hormone stimuli may exhibit increased activity during pregnancy. 5 Physical changes in benign tumors during gestation are not necessarily expressions of growth activity. 6 It is not proved that pregnancy favors the inception of malignant growth or the malignant degeneration of benign tumors. 7 Experimental evidence substantiates the clinical observations in general and permits the conclusion that pregnancy as a rule does not influence the growth rate or the size of neoplasms beyond certain reactions, of which retardation is the most frequent. In many instances it remains unaffected, and occasionally an acceleration is observed. At the termination of gestation, neoplasms assume their primary growth rate.

Effect of Posture on the Heart—Schneider and Crampton determined the output of the heart of several subjects in both the standing and the reclining position. Their results substantiate the older point of view attacked by Grollman. Without exception the subjects showed an increase in the output

of the heart after assuming a recumbent position for fifteen minutes is compared with the output while standing. Ordinarily on prolonged quiet standing the output of the heart either remains unchanged or decreases slightly in subjects exhibiting no distress as a result of the long standing. The output of the heart decreased in subjects who, on long quiet standing, display poor circulatory compensation in the erect position. A pulse pressure below 20 mm of mercury indicates a falling cardiac output.

Nontuberculous Allergy in Tuberculosis—Sherman and Egbert observed that the desensitization of a tuberculous individual to an offending protein is harmless in that it does not incite an activation of the tuberculosis. The administration of the so-called nonspecific protein, in the ignorance of the existence of the inciting atopen, will sometimes cause activation of the allergy, but not of the tuberculosis. Acquired allergy is not related to immunity. Acquired allergy is most prevalent in arresting cases of tuberculosis, in which the immunity is greatest. The evidence is in favor of the original conclusion that allergy and immunity in tuberculosis are one and the same.

Intestinal Tuberculosis—Crawford and Sawyer state that ulcerative tuberculous lesions of the intestine were found in 68.8 per cent of fatal phthisis at necropsy. Ulcerative intestinal tuberculosis was found as a complication of tuberculous pulmonary disease in 87.5 per cent in Negroes, as against 42.2 per cent in white persons. Tuberculous laryngitis occurred in 36.6 per cent of cases of intestinal tuberculosis, but 96.6 per cent of cases of tuberculous laryngitis showed intestinal ulceration. Only 10.8 per cent of the ulcers in this series were of the classic girdling type. In 540 cases of intestinal tuberculosis complicating tuberculous pulmonary disease, 53.7 per cent occurred in cases in which the duration of the pulmonary symptoms was from six months to three years. In 34 per cent of cases the intestinal lesions were asymptomatic, and in 35 per cent the duration of enteric symptoms was less than six months. Marked intestinal symptoms were not present in any cases

showing only preulcerative lesions. There were 51.6 per cent of cases classified as having had good treatment, as against 36.8 per cent of cases showing evidence of serious deficiencies in treatment. Some form of collapse therapy for the control of the pulmonary disease had been carried out in 20 per cent of the cases.

Psychoses Associated with Somatic Diseases That Distort Body Structure. Lauretta Beoder. New York.—p. 1000

Herniation of Nucleus Pulposus—Pect and Echols discuss two cases of nodules on intervertebral disks producing symptoms of tumor of the spinal cord, in the first case syndrome of involvement of the cauda equina, complete cerebrospinal fluid block, localization with iodized oil, laminectomy and removal of a nodule from an intervertebral disk with recovery and in the second case clinical signs of pressure on the cervical spinal cord, partial subarachnoid block, laminectomy and removal of a nodule from an intervertebral disk with partial recovery. The nodules removed were not tumors but consisted of nucleus pulposus tissues that had undergone secondary changes following herniation from the intervertebral disks. Herniated nucleus pulposus should be considered in cases of compression of the spinal cord that present roentgen evidence of a diseased disk at the proper level.

Premotor Area and Its Relation to Spasticity—Davison and Bieber state that an analysis of six cases of flaccid hemiplegia revealed destruction of the lower two thirds of the premotor area in five. In the other case only half of the premotor area was affected. In the first three cases, with complete occlusion of the middle cerebral artery, the degree of involvement of the premotor area was grossly identical with that observed in cases of hemiplegia with complete closure of the middle cerebral artery accompanied by spasticity. In the other three cases, with incomplete occlusion of the middle cerebral arteries the premotor cortex was not so extensively destroyed. In these cases the gray matter of the lower two thirds of the premotor area on gross examination appeared partly spared. Careful microscopic examination, however, revealed histopathologic changes. These consisted of a slight distortion of the cyto-architectural layers, small areas of destruction with a dropping out of the ganglionic cells, proliferation of the vessels and an increase in the glial elements. Clinicopathologic investigations reveal that the premotor area in man may be involved without giving rise to spasticity, and that the integrity of the premotor area is not solely responsible for the presence of flaccidity.

Tumors of Rathke's Cleft—Frazier and Alpers suggest the following revisions in the nomenclature of sellar and parasellar lesions: (1) the term hypophysis should be retained and pituitary discarded, (2) the term craniopharyngioma should be discarded in favor of tumor of the hypophyseal stalk and (3) the so-called tumor of Rathke's pouch should be designated tumor of Rathke's cleft. They attempt to establish the tumor of Rathke's cleft as a definite entity by presenting a case in which the tumor was situated entirely in the suprasellar area, with no visible connection with the third ventricle. Its structure and, in part, its location are suggestive of a congenital tumor originating from the remnants of Rathke's cleft. They believe that the feature in their case that differentiates the tumor from other tumors in the region of the sella turcica is the presence of a single layer of ciliated columnar epithelium. The possibility of the origin of these ciliated cells and cysts from the pars tuberalis of the hypophysis suggested itself, but, so far

as is known this portion of the hypophysis contains no ciliated cells. Nevertheless, the fact remains that there are in the human hypophysis ciliated cells that are found in the so-called Rathke cleft. The presence of ciliated epithelium lining Rathke's cysts was described by Erdheim in man and by Martin in rats and marsupials. The significance of these ciliated cells is uncertain. Rasmussen suggested that they may be pathologic or that "they should be looked on as unusual differentiations of hypophyseal tissues or as migrations of nasopharyngeal elements during early stages of development." The authors state that, whatever the origin of the ciliated cells may be, it is certain that at least in some human hypophyses such cells are found lining the remains of Rathke's cyst and that they conform in their morphology to the type of cell seen in their case. Theoretically, tumors of Rathke's cleft should be found within the sella turcica, but when one considers the origin of the anterior lobe from the buccal epithelium and the process of traversal and rotation during the course of its development, it is not surprising to find such tumors wholly outside the sella turcica.

Cytology of Nasal Polyps—Walsh and Lindsay examined cytologically the polyps from seventy-five cases of nasal polyposis and found that they could be divided into two types: those with many eosinophils in the tissue and those in which eosinophils were scarce or absent. Correlation of the clinical and histologic observations revealed that the polyps in the second type were invariably associated with infection in the nose or accessory sinuses, while those in the first type were often found in persons free from infection and associated frequently with demonstrable allergy. Accumulated evidence points to the fact that eosinophilia in the tissue is associated with allergy, and it is suggested that the presence of eosinophils in the nasal polyps is indicative of allergy. In cases in which eosinophilia in the nasal polyps is associated with infection, the infection is secondary in the allergic membrane or possibly there is an allergic sensitivity to the infecting organism. Surgical intervention in the two types gives different results. The results in patients with polyps having few or no eosinophils were distinctly satisfactory, while those in patients with polyps having many eosinophils were mostly disappointing. The histologic examination of nasal polyps with regard to the presence or absence of eosinophils offers a simple method of determining whether the polyps are due to infection or whether they are the product of nasal allergy. The result of surgical treatment of polyps with few eosinophils is good, but in the presence of many eosinophils it is poor.

Paralysis of Larynx Due to Lead Poisoning—Myerson collected nineteen cases of paralysis of the muscles of the larynx due to lead poisoning, to which he adds a personally observed case. A consideration of the various paralyses of the larynx due to lead poisoning leads him to question the validity of Semon's law, "that the fibers of the motor nerves going to the abductors succumb to organic affections sooner than or exclusively of the adductors." Semon believed that there was an actual biologic difference in the composition of the laryngeal muscles and nerve endings which explained the predilection of organic disease for the abductor muscles and their nerves. In the twenty cases of involvement of the larynx due to lead poisoning there were two of unilateral adductor paralysis and

no other involvement. There was one case of unilateral adductor paralysis associated with involvement of the interarytenoid muscle. A single case of paralysis of the interarytenoid muscle is included, as are also two cases of bilateral adductor paralysis. An unusual case of involvement of both cricothyroid muscles is also included, so that seven of the twenty cases showed involvement of muscles other than the abductors. These seven cases constitute a definite challenge to the validity of Semon's law.

Thermolabile Bactericidal Substance in Human Serum.

—Wulff demonstrated that a thermolabile bactericidal substance occurs in human serum, particularly during fever. Its effect was particularly seen in tests with a strain of meningococcus highly susceptible to the bactericidal substances of serum. The thermolabile bactericidal substance was found besides in some few other cases, in tests with two different strains of meningococci with three strains of Pfeiffer bacilli and with almost the same frequency as with the highly susceptible meningococcus strain in tests with a strain of *Diplococcus crassus*. The thermolabile bactericidal substance is found to occur primarily in the serum of febrile patients, in tests with a highly susceptible meningococcus strain the thermolabile substance was demonstrable in 85 per cent of the febrile patients examined, one fourth showing a marked action. The thermolabile substance could not be demonstrated in 90 per cent of the nonfebrile patients. Injection of sulfosim seems to stimulate the organism to produce a thermolabile bactericidal substance. Increase of the bactericidal substances in active serum was found in tests against a *diplococcus* strain, a phenomenon that is probably elicited only under quite special conditions. The thermolabile bactericidal substance seems to keep well in vitro. The thermolabile bactericidal substance possesses an enzymic property, since it did not become fixed in absorption tests with the meningococcus strain that was killed by it.

Low Concentration of Urea in Blood—Osterberg and Keith reviewed the records of the past four years and found twenty-five cases with widely differing ailments in which the concentration of urea in the blood was less than 10 mg per hundred cubic centimeters. For the determination of urea in the blood they used the van Slyke and Cullen modification of the Marshall urease method on whole, oxalated blood. Several patients were suffering from a serious chronic disease, such as pulmonary tuberculosis, encephalitis, diffuse skin lesions, chronic suppuration, diabetes mellitus, duodenal ulcer and Addison's disease. In some cases also there were chronic renal lesions, these including bilateral pyelonephritis, bilateral hydronephrosis tuberculosis of the kidneys, and the diffuse nephritis associated with disseminated lupus erythematosus. The occurrence of a low value for urea in the blood in diabetes insipidus would seem to be a possible result of the enormous water exchange. Similarly, in diabetes mellitus the low value for urea might be the result of polyuria. In duodenal ulcer with obstruction the water and inorganic metabolism may be upset markedly, but it can be corrected readily by large intravenous injections of fluid. In this condition also a low value for urea in the blood might be the result of a large intake of water. However, in other cases no definite organic lesions or marked physiologic disturbances were demonstrated, and the symptoms were described as being due to nervous exhaustion. The occurrence of an abnormally low content of urea in the blood in cases with bilateral renal disease seems rather paradoxical. In a case of disseminated lupus erythematosus the value for urea was 6 mg per hundred cubic centimeters, the patient was taking in and excreting a considerable volume of water, but the diet was inadequate. The most plausible explanation is that during a temporary process of healing in the kidneys, urea and water were readily excreted and the production of urea was decreased. In a case of chronic pulmonary tuberculosis in which albuminuria and cylindruria developed during the last month of illness the value for urea in the blood was 6 mg per hundred cubic centimeters, and at necropsy there were no demonstrable histologic abnormalities in the kidneys. Thus it is possible to have a very low value for urea in patients with abnormal kidneys whether the renal disturbance is due to demonstrable histologic changes or to physiologic abnormalities.

Indicator for Estimation of Chlorides in Blood—Shapiro prepared a stable starch indicator with the use of acetylsalicylic acid and methenamine as preservatives. It was found to keep in the original state for several months. Comparative tests indicated that it may be used safely in iodometric

methods for chlorides in blood and urine. The tests further show that this indicator works well when the specimens themselves contain the foregoing preservatives.

Medium for Isolation of Bacillus Typhosus from Feces—Sellers and his associates find that the bismuth sulphite medium as devised by Wilson and Blair is superior to the endo medium as a means of laboratory detection of *Bacillus typhosus* in feces. They discuss the preparation of the medium, its practical application and its advantages and disadvantages. They especially recommend bismuth sulphite medium for use in state and municipal laboratories in which the detection of typhoid carriers among food handlers and dairy workers is an important feature.

Pertussis in Adults—Mannerstedt states that, in a recent epidemic of pertussis, chronic coughs in adult contacts were sufficiently common to suggest a study of the cases to determine whether or not *Haemophilus pertussis* was an etiologic factor. A thorough history covering all the anticipated characteristics was taken in all adults (twenty-nine, aged 24 years or more) presenting themselves with a chronic cough. This was supplemented by careful follow-up notes. Blood counts were taken when the patients were first seen and periodically from every two to five days during the clinical course. Cough plates were taken when feasible and, after adequate incubation, thoroughly examined bacteriologically. The author observed that, in adults, pertussis starts with an insidious cough from one to three weeks after exposure. This cough lasts from five to six weeks or longer. It is worse at night and is intensified by such factors as exertion, excitement, eating and temperature changes. Whooping and vomiting are infrequent, but gagging and choking are common. A thick, white, tenacious phlegm is raised. Positive cough plates were obtained in six cases. The clinical picture and blood studies were similar to the remaining cases. The blood count in adult pertussis is not as characteristic as in the juvenile cases and usually is of no value in diagnosis.

Diphtheritic Myocarditis—Hoyne and Welford point out that in 496 cases of myocarditis which developed in 4,671 diphtheria patients there was a fatality rate of 62 per cent. The fatality rate was 75 per cent during the age period from 1 to 5 years, 54 per cent from 6 to 10 years, 50 per cent from 11 to 15 years, and 43 per cent in those older than 15 years. The mortality was highest (70 per cent) in cases in which there was nasal involvement and lowest (11 per cent) in simple tonsillar diphtheria. Of all deaths from diphtheritic myocarditis, 79 per cent occurred during the first fourteen days of the disease, the average day on which death occurred being the tenth. Abdominal pain and vomiting with a falling pulse rate and blood pressure were signs of grave prognostic importance. The malignant type of diphtheria was an important factor in accounting for the high mortality rate. The most important pathologic change in 126 necropsies was extensive toxic myocardial degeneration. Epinephrine and caffeine were of no value as permanent circulatory stimulants. Parenterally injected dextrose solution seemed to be a life saving measure in some cases of severe diphtheritic myocarditis.

Rheumatic Encephalitis and Tribrom-Ethanol—Frisch presents the case of a most severe type of chorea, so-called chorea insaniens, which occurred shortly after the course of a rather mild acute rheumatic fever. The involvement of the central nervous system was widespread and severe, evidenced by a most marked motor activity and severe emotional disturbance, and by hyperpyrexia and cyanosis, which were probably of cerebral origin. During the course of the severe nervous disturbance, there was progressive cardiac involvement, indicated first by an incomplete heart block, followed by a definite pericarditis with effusion. After the acute central nervous system involvement had subsided, residual nervous phenomena resulted. These phenomena consisted of fixation of the eyeballs in a downward gaze, with inability for ocular motor activity in any direction—an evidence of basal ganglion disease affecting ocular motor control. Because of the newer knowledge of the pathology of chorea, the clinical features of his case and its close relationship to the rheumatic virus the author believes that the designation of the condition as rheumatic encephalitis is justified. After other sedatives had failed to produce any result, rest and relaxation were obtained by tribrom ethanol. This was administered rectally in a dosage of 80 mg per kilogram of body weight. During the quiet periods produced by the anesthetic, nourishment and other therapeutic aids could be administered.

Treatment of Angina Pectoris by Ablation of Thyroid

—In the course of the last eighteen months, Berlin and his associates have treated seventy-five patients with various types of chronic heart disease by total ablation of the normal thyroid. In an attempt to reduce the operative mortality and postoperative complications to a minimum anatomic and surgical studies have been made of the parathyroid bodies and the recurrent laryngeal nerves. The value of various anesthetics has also been studied. As a result of these studies, improvements in surgical and medical management have been effected and the last thirty-six consecutive operations on patients with chronic heart disease have been performed without mortality. They discuss the surgical problems that should be considered in the technique of the operation: the parathyroids, recurrent laryngeal nerves, the necessity for total ablation of the thyroid, the choice of anesthesia, the selection of patients and changes in preoperative and postoperative treatment, the preoperative basal metabolic rate and coronary thrombosis. They give the results of total thyroidectomy for the treatment of chronic rheumatic heart disease and compare with them those obtained in the

treatment of arteriosclerotic heart disease. They believe that the beneficial results that have been achieved by total ablation of the normal thyroid in patients with angina pectoris and recurrent congestive failure warrant the further application of this procedure in patients who are incapacitated in spite of all available medical treatment.

*Presence in Egg White and in Rice Polishings Concentrate Low in Vitamin B₂ (G) of Antipernicious Anemia Principle D K Miller and C P Rhoads, New York—p 921
*Leverage Reduction in Fractures of Surgical Neck of Humerus. F J Cotton and G M Morrison, Boston—p 924

Antipernicious Anemia Principle in Egg White—The observations of Miller and Rhoads indicate that, contrary to the conclusion of Wills, the dietary antipernicious anemia factor is present in egg white, hence they fail to substantiate the conclusion of Wills that the antipernicious anemia factor and vitamin B (G) are dissimilar. That vitamin B₂ (G) and the antipernicious anemia dietary constituent are identical is also not justified, since egg white may well contain an almost infinite number of substances other than the vitamin. The results of an experiment in which a clear cut increase of reticulocytes and improvement of blood values followed the administration of an amount of rice polishings concentrate containing only 75 units of vitamin B₂ (G) are clear cut. If vitamin B₂ (G) is the active principle it must be effective in an exceedingly low concentration, since in two experiments no more than 100 and possibly as few as 20 units daily was sufficient to effect a response. In one experiment an amount of material containing only 75 units daily was effective. The difference in weight between the largest rats employed and an average adult human being is as 1 1,400. Conclusive proof of the identity or lack of identity of the dietary antianemic factor and vitamin B₂ (G) must be deferred until isolation of the vitamin in a pure form.

Fractures of Humerus—The form of reduction that Cotton and Morrison are using for fractures of the surgical neck of the humerus is as follows. Finger and roentgen examination are done in order to define the relation of fragments. Then the patient is anesthetized and placed on his back. Strong steady pull is exerted downward on the wrist (arm in extension) with a hand grip or with a clove hitch about the wrist, for at least five minutes. Then the operator thrusts his arm through the axilla and, with his hand flat on the table beneath the patient's scapula, uses his forearm as a lever to pry the humerus outward. This is to overcome the spastic pull of the great pectoral muscle. When this spasm eases off, the assistant adducts the straight arm to the midline and forward (upward as the patient lies) while the surgeon, with the position of his arm almost unchanged, uses this arm as a lever to pry the upper end of the lower fragment out and backward. After one or two maneuvers of this sort, something moves, this is checked roentgenologically and the maneuver is repeated or varied as indicated. If reposition is fairly exact, the tendency to redisplacement is small and no apparatus other than a sling and a circular swathe is needed. Motion may be begun early (one week). Pendulum exercises are most useful with the arm hanging free, the patient doing the swinging. The authors cite three typical cases as ordinary routine examples.

Epilepsies Associated with Endocrine Disorders—Turner demonstrates the importance of endocrine dyscrasias as an etiologic factor in the causation of epilepsy. He presents cases illustrating endocrine (parathyroid, pancreas, suprarenal and hypophysis) disorders in the convulsive states relieved by endocrine therapy. Calcium metabolism is regulated by the parathyroids. One of the prominent actions of calcium is on the excitability of the nervous and muscular systems. This is evidenced in parathyroid tetany by marked nerve and muscular hyperirritability due to a lowered calcium balance. Calcium by mouth is indicated in the parathyroid and infantile types. The role of the pancreas and disturbed sugar metabolism as a causative factor in epilepsy has been demonstrated by Seale Harris and others. They have proved conclusively the definite association of convulsive states with hyperinsulinism and other hypoglycemic conditions. The majority of cases of functional hypoglycemia may be treated by frequent feedings or by a diet high in fat, which has a depressing effect on the pancreas, or with solution of pituitary, which is an antagonist of insulin. Hyperinsulinism due to neoplasms of the pancreas is best treated by operative procedures. Myasthenic, narcoleptic and epileptic episodes are frequent sequels of suprarenal insufficiency. In Addison's disease fatigue, insomnia, mental aberrations, nervous irritability and convulsive seizures occur commonly. Their immediate relief following injections of extracts of suprarenal cortex is striking. In other hyposuprarenal conditions epinephrine, the hormone of the medulla, may be equally efficacious. The relationship between the hypophysis and epilepsy was established when an anatomopathologic examination in cases of epilepsy revealed changes in the pituitary. A typical case is the one reported by Kryloff. The rather frequent occurrence of physiologic and morbid changes in the hypophysis, thyroid, suprarenals and other incretory glands in cases of epilepsy gives an indication of the relationship of these glands to this condition. It is an established fact that there is a definite functional relationship, and one is readily able to suppose that convulsive crises may be lessened by a normal physiologic balance and aggravated by a condition that produces an abnormal or toxic pituitary secretion. This may readily explain the numerous cases of thyroid origin and their relief by the administration of thyroid or by thyroidectomy, accompanying changes in the suprarenals and relief by suprarenal substance and by denervation, and the convulsive action of insulin, which is partially counteracted by the injection of solution of pituitary.

- *Streptococcus Bacteriophage Study of Four Serologic Types Alice
C Evans—p 1386

Serologic Types of Streptococcus Bacteriophage—Evans describes four serologic types of streptococcus bacteriophage, designated A, B, C and D. Their distinct behavior in cross serologic reactions is the only character that clearly

differentiates them. The virulence of a lytic filtrate for a given strain of streptococcus depends on the sensitivity of the strain and varies with different strains. When kept in a refrigerator protected from the air, streptococcus bacteriophage retains its virulence for years. Exposure hastens its deterioration. The addition of phenol or merthiolate in quantities used ordinarily for preservation also hastens its deterioration. There was no notable difference in the deleterious effect of the two preservatives. The inactivation temperature for streptococcus bacteriophage lies between 60 and 65 C. There is a slight but definite difference in the inactivation temperature of the several types of bacteriophage. Bacteriophages A and B were inactivated at 60, bacteriophage D at 63 and bacteriophage C at 65 C. The size and the nature of the plaques formed on agar cultures depend on the streptococcus that forms the substratum as well as on the type of the bacteriophage. Secondary cultures were generally resistant to lysis by filtrates homologous to that in which growth occurred. In the nascent state (in the presence of a sensitive strain) streptococcus bacteriophage will attack strains that are resistant to the filtered lysate. The four races of bacteriophage in the nascent state were examined for ability to attack 421 strains of hemolytic streptococci. Bacteriophage A lysed 89.3 per cent of strains, B, 88.4, C, 79.3, and D, 9.7 per cent. In general, pneumococci were more sensitive than hemolytic streptococci to the four types of bacteriophage in the nascent state. None of the few strains of the alpha type of streptococcus examined were sensitive to the bacteriophage. Among the few strains of *Streptococcus lacticus* examined, one was found sensitive to bacteriophage D and one of a few strains of staphylococcus was found sensitive to bacteriophage A. According to their sensitivity to the four races of bacteriophage, the strains of hemolytic streptococci fell into eight groups, the largest of which agree in a general way with groups already recognized as species on the basis of other characteristics.

Roentgenologic Study of the Duodenum.—Shiffer employs a tube 106 cm in length and 6 mm in diameter for roentgenologic study of the duodenum. The tube is divided longitudinally into two lumens by a rubber partition, one leading to a balloon at its distal end and the other to an opening just proximal to the attachment of the balloon. A duodenal bucket at the distal end of the tube over which the balloon is attached is employed for the purpose of making the localization of the distal end of the tube under the fluoroscope easier. A Luer syringe is used to inject air, usually about 40 cc., into the balloon. The size of the balloon and the amount of air necessary to distend it are tested prior to each intubation. When the balloon is in place it is distended with air. A

barium mixture is then allowed to run from a small vessel by gravity into the duodenum proximal to the balloon, the speed of flow being regulated by the height of the reservoir. The patient is intubated after a fast of from twelve to fifteen hours. The time required for the balloon to reach the duodenum varied from one-half to one and a half hours. This time can be shortened if fluoroscopic control and manual manipulation are used. It is well to have 1 or 2 inches of slack tube in the stomach so that it does not hug the lesser curvature of the stomach too closely. The ideal place in the duodenum for the balloon is in the third or fourth portion. The purpose of the examination will be defeated if too much air is used at first. Undue stretching of the duodenal wall will initiate violent reverse peristalsis with regurgitation of the balloon. A complete obstruction should not be done at first, as an acute lesion may be present. Caution must also be used when the barium is allowed to run in so that a too sudden increase of pressure in the duodenum is not caused. Sufficient air to distend the balloon to a diameter of 2.5 cm. should be injected at first, and then the barium mixture is allowed to run in slowly if a small amount of the barium escapes beyond the balloon, more air may be introduced slowly until the opaque substance can be seen to fill the proximal duodenum. Fluoroscopic observations are made continuously while the cap and the rest of the duodenum above the obstruction are being filled, films being exposed at any desired times. The tube is withdrawn after deflation of the balloon at the end of the examination. In a series of thirty patients, twelve normal and eighteen pathologic, the author observed that sometimes certain lesions not clearly recognizable by the ordinary roentgenologic methods may be identified. In these cases the foregoing technic confirmed the diagnosis of a normal duodenum in twelve, duodenal ulcer in seven and differentiated adhesions from ulcers in four ruled out both ulcers and adhesions in three, and demonstrated a cholecystoduodenal fistula in one, a dilated ampulla of Vater in three, duodenal occlusion or stasis in three and an enlarged head of the pancreas in one.

New Encephalographic Technic—Castex and Ontaneda submit an encephalographic technic based on the existing difference of tension between the fundus of the dural cavity and the cisterna magna, when the patient is sitting up. The principle of the method is that, if a glass container filled with air is connected to a needle inserted into the cistern and another needle in the dural cavity, the lumbar liquid will pass into the glass container because of its higher pressure, will dislodge the air harbored in it and then will send this air into the cistern and finally into the endocranium, without practically altering the endocranial tension. The results that they obtained by this method in about 100 cases are satisfactory and they believe that it is just as innocuous as ventriculography or more so, and much more than encephalography, thus compensating for its greater technical complexity.

Blood Pressure of Typhoid Carriers—Forsbeck observed that a chronic typhoid carrier of long standing is more likely to have hypertension than a person of the same age in the general population. The arbitrary limit of normal systolic blood pressures is placed frequently at 140 mm. The mean systolic pressure even for those older than 60 years is but 135.2 mm. On the other hand, of forty carriers of long and short standing, 55 per cent had a systolic pressure above 140 mm., the mean systolic pressure of the group being 155 mm. An elderly group of twenty-seven persons in a county home, many of whom had arteriosclerosis, had a mean systolic pressure of but 145 mm., whereas twenty-seven carriers with the same mean age had an average pressure of 175 mm. In the eleven carriers who had typhoid before 1911 the lowest systolic pressure was 158 mm and the mean 197 mm.

Gangrene Following Fractures—Dodd states that gangrene may follow after several types of injury to the main artery of the limb. 1. Complete division of the chief vessel by sharp or blunt trauma. 2. Penetration of the principal artery, e. g., by a fragment of bone, groups 1 and 2 usually result in cessation of the blood supply by thrombosis or by the formation of a diffuse traumatic aneurysm. 3. Contusion or rupture of the intima or of the media and the intima together, leading to vascular obstruction by thrombosis. 4. Embolism by a thrombus that has originated in the artery at the level of the injury becoming detached and lodging more distally as an embolus, it is usually located at a bifurcation, e. g., at that of the popliteal artery. A condition of segmentary vessel spasm may also result in threatened or actual gangrene. In the diagnosis of injury to and occlusion of a main artery, all or various combinations of the following signs and symptoms may be found. 1. Presence of pulsation above the injury, with impairment or loss of it below this level. 2. Below the traumatized place an alteration from the normal sensation. 3. Blanching, cyanosis and stone coldness of the limb below the injured area. Later bullae and large blebs may form on the skin. 4. Loss of muscle power e. g., inability to make the slightest movement of the foot or toes after a fractured tibia, even with considerable effort. 5. Presence of a hematoma and bruising about the vessel. This may not be apparent immediately on inspection but if the part is palpated by the fingers, the tension will be detected. 6. Sometimes tenderness and pain localized precisely over the chief vessel at the point of injury, this suggests thrombosis. 7. Gradual fall in the blood pressure of the limb as compared with the systemic figure denoting failing local circulation. Careful inspection of the roentgenograms may reveal signs of calcified arteries. When the onset of gangrene following a fracture is suspected in view of the inevitable amputation when it occurs surgical intervention, even though it may be heroic, is justified. The systemic indications of diseased arteries and especially the foregoing signs of interference with the circulation in a limb, should be watched for in all bone injuries. When the symptoms have appeared and have not subsided shortly wide exploration of the main vessels at the site of injury is suggested. When the vessels have been defined the further procedure will depend on the changes found on the patient's condition on the surgeon and on his equipment. One of several operations may be necessary. He presents cases of noninfective gangrene following various fractures.

Fibrosis of Testicle of Filarial Origin—Ray reports a case of chronic epididymo orchitis of nonvenereal origin. In the differential diagnosis of the case new growth of the testicle, diffuse tertiary syphilitic orchitis or gumma, hematocele and epididymo-orchitis of filarial origin were taken into consideration. The insidious onset, tardy rate of growth, history of venereal disease, moderately positive Wassermann reaction and the firm consistency of the swelling were points in favor of a diffuse syphilitic orchitis rather than a gumma. The points against it were the presence of testicular scurction, lymphangiectasis of the spermatic cord and the history of two previous attacks of pain in the testicle with successive increase in size. These points were in favor of a filarial complication. The testicle was adherent to the scrotum anteriorly, presenting a small fluctuating area, through which about a drachm (4 cc) of sterile necrotic fluid was evacuated. During the patient's four weeks in the hospital, the course of the disease was apyrexial. The blood report showed an eosinophil count of 2 per cent, but no definite cause could be discovered to explain it. The blood was not examined again for the microfilaria. The testicle was removed by operation. The testicle and epididymis, which was converted into a necrotic mass, were embedded in a connective tissue matrix surrounded by a thick fibrous capsule, obliterating the vaginal sac. Microscopically, sections of adult female worms (*Filaria Bancrofti*) and numerous microfilariae, contained within the uterus, were seen in the tunica albuginea. Degenerating adult filariae were also seen in the epididymis. No evidence of secondary pyogenic infection could be adduced. The conclusion reached was that the adult filaria was the real cause of the pathologic changes in the testicle. The condition has been described under the name of chronic epididymo-orchitis or fibrosis of the testicle of filarial origin.

Cholecystitis Without Stone—From a study of 243 cases of cholecystitis without stone and twenty-one cases of cholesterosis of the gallbladder accompanied by gallstones, Mackey observed that in cases of cholecystitis without stone, cholecystectomy carries a mortality of 3 per cent. Cure of symptoms results in 30 per cent, and improvement in 30 per cent. In 37 per cent the end result of operation is unsatisfactory. Cholecystitis without stone seems to belong to a region on the borderline between functional and organic disease. No single test is infallible, though, in the individual case, study of the clinical history, the cholecystogram and subsequently the microscopic sections may each yield information pointing toward or away from the gallbladder. The results of cholecystectomy indicate that it is dangerous to overemphasize any one of these methods of investigation or to attribute importance to minute details. To establish a diagnosis of cholecystitis the history must be typical and should include pain. No evidence has been obtained that either flatulent dyspepsia or food selection necessarily indicates gallbladder disease or is likely to be relieved by the removal of the gallbladder. Cholecystographic changes must be definite and mere impairment of the density of the gallbladder shadow does not mean invariably that the gallbladder is pathologic. While almost every gallstone will be revealed by the use of the dye test, the same degree of precision is not attained in the field of stoneless cholecystitis. Microscopic changes are probably not significant unless they are fairly gross. Cholesterosis of the gallbladder is not of itself a pathologic or symptom-producing condition. A considerable proportion of patients are unrelieved by the removal of a stoneless gallbladder, the therapeutic failures are due to symptoms having their origin outside the gallbladder. The appendix, however, does not seem to be the organ responsible. The results of surgical treatment of cholecystitis without stone are relatively unpredictable in the individual case, even by the most modern of laboratory procedures. Certainly they are not so good as in the presence of gross organic disease, when generally speaking, symptoms are clamant and relief after operation is dramatic.

Nephritis and Necrosis of Liver from Di-Ethylene Di-Oxide Poisoning—Barber cites the records of five men who died as the result of working in a process in which di-ethylene di-oxide was used. The morbid anatomy was proved, by necropsy, to be hemorrhagic nephritis in four cases associated with central necrosis of the liver, which was proved by histologic examination in three cases. There is evidence that a few intense exposures to the chemical toxin are much more serious than repeated slight exposures. It is suggested that the kidney disease was the more serious condition and was responsible for the fatal termination. It is possible that the liver necrosis, although widespread, was compatible with recovery. The morbid anatomy and histology show such acute damage to the kidneys as to suggest one large dose of the poison absorbed from the stomach. But it was concluded that absorption was by inhalation. The most feasible explanation is that after the process was intensified some liver necrosis was taking place day by day, unsuspected in the absence of jaundice and that, when the toxipylactic action of the liver failed, the poison passed on to the kidneys. In no case was there jaundice to indicate damage of the liver, but the early symptoms of the fatal illness are compared with short attacks of stomach trouble, which are attributed to sublethal doses of the poison producing some liver necrosis, from which recovery took place. The fatal illness lasted about a week, from the third day of which uremia was predominant. There is little evidence of disease from chronic poisoning, but those exposed to the chemical showed a definite increase of leukocytes, particularly the neutrophils. The absence of fatty change in the liver of the fatal cases is quite different from what is found with other known liver poisons, such as alcohol and chloroform.

Manipulation in Treatment of Lower Back Pain—Stamm points out that the possibilities of manipulation as a method of treatment are limited. Only two purposes can be achieved by its employment: (1) the replacement in apposition of displaced articular surfaces in dislocations and subluxations and (2) the breaking down of obstructions to movement. Pain in the back may be produced by the stretching of fibrous or scar tissue, by localized pressure, as when two bony points become impacted, and by congestion, which acts by causing intercellular tension, as in the pain of inflammation. The pain associated with the stretching of fibrous or scar tissue is characteristic. It is induced by activity and becomes steadily worse until rest is taken. The pain associated with a subluxation is also of the first variety. As the articular surfaces are no longer in correct apposition, certain of the ligaments of the joint must be under increased tension and this may persist even at rest. The pain therefore tends to be of a more continuous nature, and the congestive element is frequently present. The pain of localized pressure plays a much less important part in these cases and is usually associated with gross organic changes. In most cases the affected bony projections can be identified either by palpation or by roentgenograms and it is found that movements which tend to separate them will relieve pain and vice versa. There is little scope for manipulation in the majority of cases of this type. Lower back pain which has its cause in the congestion of inflammation is similar in character to pain in other parts of the body attributable to the same cause. It takes the form of a continuous ache, made worse by activity and persisting even during rest. It is not relieved by alterations of position. It is characteristic of this type of pain that a feeling of stiffness in the part is experi-

enced after a period of rest, and the first movements are the most painful. Manipulation in cases of this character requires careful consideration. In subluxation manipulation affords the only rational line of treatment and gives satisfactory results. The majority of patients are afforded instant and complete relief. In acute and chronic sprain the adhesions and scar tissue can be broken down by manipulation and full mobility restored. There are then no structures to be put on the stretch, and the pain is relieved. At this stage exercises are beneficial, because by their means the restored mobility is retained and adhesions are prevented from reforming. In chronic strains, the result of inadequate muscular function, muscular reeducation, together with the correction, after careful analysis of faulty posture associated with and related to occupation is indicated. Manipulative treatment is merely an important incident in the general scheme. In cases of focal infection, the infection is dealt with first. Then, if the pain persists, manipulation may be performed. The results in the majority of doubtful cases show that the pain is relieved considerably by the manipulation, indicating that no active inflammation was present. Cases of sacro-iliac contusion derive no benefit from manipulation. Prolonged immobilization in a plaster cast would appear to be a more rational line of treatment. In all cases of possible damage to bone or cartilage in which manipulative treatment is contemplated, preliminary roentgen examination is of the utmost importance. Manipulative treatment must not be undertaken for osteo-arthritic cases as complete ossification of the spine may occur. In acute cases of true primary sciatica and in those cases in which the pain has been present for only a short time, manipulation should be avoided. In long standing cases however, in which it is probable that the pain has been perpetuated by the presence of adhesions, it is not of itself a contraindication to manipulation, which is often followed by considerable relief from pain.

New Method of Study of Brain Capillaries—Although more than 1,000 sections of brains of mental patients have been examined, Pickworth considers the work still in its preliminary stage. Although it is stated that the cerebrum is one of the most vascular of organs, he has found that the vascularity of the brain is far less than for instance that of the kidney (about one sixteenth), which is surprising in view of the vascularity of the brain membranes but understandable since a large proportion of the brain substance consists of organic soluble "electrical insulating" material. The preponderance of vascular abnormalities is in the cerebral supply, amounting in many cases to almost complete anemia. In many cases it is the sub-cortical part of the brain that is almost devoid of normal staining hemoglobin, merely the shell of the cortex showing the vessel stain. I.e., early stage of general softening of the brain. These and the smaller ischemic areas indicate neighboring brain paralysis, congestion may be associated with increased irritability of brain tissue. Loss of brain substance follows continued ischemia which becomes evident as a reduction of thickness of the cortex or as changes in pattern of the

architecture, owing to the plastic nature of brain substance, the volume of any given focal lesion becomes greatly reduced in the course of time. Quite commonly the author has found softenings of the brain, unsuspected during life, which vary in size from microscopic areas to an inch or more in length. These occur in any part of the white matter of the brain and its stem. Capillary hemorrhages are commonly seen, occurring in great numbers in the basal ganglions of the few cases that he has examined which during life showed choreiform symptoms. Abnormalities of the tissues adjacent to the lateral and third ventricles are not uncommonly present, and often thick walled tortuous vessels in the basal ganglions are the seat of pathologic changes sometimes accompanied by masses of yellow brown granules.

Posterior Inferior Cerebellar Thrombosis—Hall and Eaves report a case of left posterior cerebellar thrombosis belonging as regards distribution of sensory loss, to the less common type in which sensation is affected entirely on the side opposite the lesion. The loss of tactile sensation, as well as sensations of temperature and pain over the whole contralateral side is in marked contrast to all previously recorded cases, in which the loss has been dissociated only. The left posterior inferior cerebellar artery was smaller than usual, the left anterior inferior cerebellar artery was unusually large. An area of degeneration corresponding to the distribution of the left posterior inferior artery was consistent with an occlusion of that vessel three months before death. It was smaller than usual. No other appreciable area of degeneration was found in any part of the brain stem. The degeneration of the spinothalamic tract could be traced only as far as the lower part of the pons. The authors suggest that in this man tactile impulses from the opposite side traveled through the medulla either with or closely adjacent to those of pain and temperature.

Immunization Against Yellow Fever—Findlay states that the presence of active neurotropic yellow fever virus circulating in the blood stream during the course of immunization renders the patient concerned a potential danger both to himself and to the community if any of the known mosquito vectors of yellow fever are present. Although Mathis, Laigret and Durieux state that their mass experiments were not followed by any epidemic outbreak, this does not alter the fact that, as shown by the experiments of Davis, Lloyd and Frobisher, and of Roubaud and Stéfanopoulou, *Aedes aegypti* is capable of taking up the neurotropic virus from the blood stream of monkeys and retransmitting it to other animals. Davis has recently shown that at each bite the stegomyia mosquito injects approximately 100 times the infective dose for the mouse. The chief personal danger to which a person with active circulating neurotropic virus is exposed is that the barrier between the blood stream and the brain may be broken down and the central nervous system may be invaded by the virus. This appears to have occurred in two cases reported by Laigret. It certainly occurred in one of the monkeys inoculated in the course of the present investigation. Davis, Lloyd and Frobisher also record the case of a monkey that developed encephalitis following the bite of a mosquito infected with the neurotropic virus. Occasionally also mice and guinea-pigs inoculated intraperitoneally with neurotropic virus have developed encephalitis in the absence of any known cerebral trauma. Therefore the barriers between the blood and the brain cannot be regarded as always impermeable to the neurotropic yellow fever virus. A second danger which cannot be excluded entirely is that the neurotropic strain may revert suddenly to the viscerotropic virus. In man following the inoculation of neurotropic virus, leukopenia and bradycardia are common, while symptoms such as albuminuria and jaundice have been recorded also,

and in hedgehogs Findlay and Clarke have shown that subcutaneous inoculation of neurotropic virus is capable of producing lesions in the liver and stomach similar though rather less in degree than those produced by the viscerotropic virus. The neurotropic virus should be regarded as pantropic rather than strictly neurotropic.

Subcapsular Cataract in Osteomalacia—Pi reports four cases from the observation of which there can be no doubt of the existence of cataract in osteomalacia. It is a subcapsular type of cataract similar to that observed in postoperative tetany. In the first case the capsular and subcapsular cataracts existed at the same time. Usually the subcapsular cataract exists alone. In the first two cases the lenticular opacities were in the form of radiating spokes and irregular patches. In the last two cases the lenticular opacities were composed of very fine dustlike dots confined to the subcapsular layers of the lens. In spite of the severe changes that took place in the lens of the second case the visual acuity remained still more or less normal for both near and far distance. In the third case the vision for both near and far distance was reduced, although the patient was not aware of the disease at all. In the first case there was blurring of the vision for a duration of five years. The cataract seems to have been a slowly progressive disease unlike the cataract in postoperative tetany, which, according to the observations of different authors, usually runs a rapid course. The lenticular opacities during the time of observation were reduced after the administration of thyroid hormone, which is usually not effective in postoperative tetany cases. Tetany was not observed in the third case, and even Chvostek's and Trousseau's signs were absent. The author's opinion is that the formation of cataract in tetany cannot be the result of tetany itself but rather the effect of deposition of calcium phosphate in the lens. He recommends that the term cataracta tetanica should be discontinued in reference to the disease since the cataracts are developed either with or without tetany and since tetany of the other diseases such as epilepsy, gastric disturbance and tetanus, does not produce any changes in the lens. In place of this general term he suggests cataract in osteomalacia or adult rickets cataract in rickets or cataract due to hypoparathyroidism and so on.

- *Undulant Fever and Tuberculosis L Bernard —p 1617
Eczema of Nursing and Allergy A Szary —p 1619
Criterion of Treatment of Gastro-Intestinal Ulcer in Medical Therapeutics C Bonorino Udaondo —p 1621
Meincke Reaction in Colonial Practice S Golovine —p 1624

Undulant Fever and Tuberculosis—Bernard considers the differential diagnosis of these two conditions and their possible association. He believes that the cases involving difficulties of differentiation may be classed in five categories. 1 Undulant fever simulating tuberculous infiltration. The principal symptoms are asthenia, pallor, emaciation and sweats beginning insidiously usually in young persons and progressing persistently with resistance to all treatment. 2 Pulmonary forms of undulant fever. These may be subdivided into an acute type of pulmonary congestion, a corticopleural type and pleurisy with effusion. 3 Undulant fever cachexia. This occurs in prolonged undulant fever when the general condition is so profoundly affected as to simulate tuberculosis. 4 Acute forms. In this type, undulant fever may be confused with miliary tuberculosis. 5 Localized types. In this group, localization in the articulations and elsewhere may resemble those which are characteristic of tuberculosis. The association of the two conditions has been confirmed by numerous observations. He concludes that the two conditions may be easily confused and may also be associated. The confusion may be clarified by careful clinical analysis and especially by blood culture, agglutination reaction and intradermal reaction. Recent epidemiologic inquiries have demonstrated the progressive frequency of undulant fever, and it is important to know that this condition produces a new group of "false tuberculosis."

42 1641 1656 (Oct. 20) 1934

- *Action of Urinary Extracts on Rabbit Suprarenals and Its Application to Diagnosis of Cancer G Roussy, C. Oberling and P Guerin —p 1641
Nature Place and Interpretation of Roentgenologic Symptomatology in Cardiology D Routier and R Heim de Balsac —p 1642

Urinary Extracts in Diagnosis of Cancer—Roussy and his collaborators have applied the urinary-suprarenal test of Aron for cancer to seventy patients with and without cancer. It is supposed by Aron that the urine of cancerous patients, when injected into rabbits, contains a specific principle which causes the excretions of lipoids from the suprarenals. The method consisted in preparing an alcoholic extract from 25 cc. of fresh urine, drying this extract, redissolving it in a small quantity of physiologic serum and injecting it under the skin of a rabbit. The same process is repeated daily for three days and the animal is killed forty-eight hours after the last injection. The suprarenals are fixed and stained and sections are cut. In a "positive reaction" the spongocytes of the suprarenal cortex have lost most or all of their fatty inclusions, they seem dark and the difference between the normally clear fascicles and normally dark reticulum tends to be abolished. In twenty-nine of their seventy cases, the results were doubtful, this does not exceed the limits of normal variability. In a group of twenty-one positive cases there were thirteen cancers, one lymphogranulomatosis and seven noncancerous conditions. There were twenty negative reactions in ten cancerous and ten noncancerous patients. These results combined with others led the authors to the conclusion that the test cannot be used in the diagnosis of cancer.

- *Studies on Physiologic Properties of Anterior Pituitary Like Principle A Brindeau H Hinglais and M Hinglais —p 1657
Biliary Chlorine E Chabrol R Charonnat, J Cottet and M Caehin —p 1660

The Anterior Pituitary-Like Principle—The separation of the follicle stimulating and luteinizing factors of the anterior pituitary-like principle present in the urine of pregnant women according to Brindeau and his co-workers, has never been completely realized. They have attempted to resolve this difficulty by using the titration method for the luteinizing factors described by Hinglais and Brouha, by which the specific action of this factor on the genital tract of the male mouse is utilized.

They have also employed the Zondek titration method for the follicle stimulating factor, using the prepuberty female. In this manner they were able to obtain preparations rich in one factor and poor in the other. The physiologic effects of these preparations were tested on prepuberty female mice, prepuberty male mice and rabbits. Also the successive and combined action of the preparations was tried. The results led them to the conclusion that the hypothesis concerning the two factors present in the anterior pituitary-like principle is correct. They also confirmed the conclusion that the isolated luteinizing factor does not act on the ovarian follicle unprepared for its action. They believe that the anterior pituitary-like factor is a system of complex hormones comprising at least three elements, viz, a hormone of follicular maturation, a hormone of follicular sensitization, and a so called hormone of luteinization. These three hormones are not bound to each other in the natural products or active extracts in any constant quantitative relation.

- *Elephantiasis of Rare Localization. Case. E. Leo—p. 227
Experimental Surgery of Parathyroids. C. Rossi—p. 251
Intramural and Interstitial Forms of Calculus of Gallbladder. B. Baroni—p. 273
Histopathology of So-Called Cysts of External Menisci. L. Santa—p. 338

Elephantiasis of the Back—Leo reports the case of a woman, now 29 who suffered a trauma when between 6 and 7 that caused neither immediate alterations of the tegumental tissues nor inflammatory complications but was followed by the development of elephantiasis to such an extent that the whole back was involved. None of the causes considered in the pathogenesis of elephantiasis or the factor of heredity were found in the clinical history. Her somatic and psychic characteristics indicated the presence of a grave complex endocrine dysfunction, especially of the thyroids and of the hypophysis, which the author believes was the predisposing factor for the development of the disease. Trauma and the mechanical factor of gravity acted as secondary agents. The author presents a critical review of the various surgical treatments of elephantiasis among which he prefers Gaetano's operation: complete removal of the subcutaneous, edematous and infiltrated tissues and partial removal of the muscular aponeurosis which results in a modification of the venous and the lymphatic circulations. He followed the general principles of Gaetano's operation satisfactorily, with some modifications, however, because of the site of the disease.

Calculus of Gallbladder—Baroni reviews the history and literature of Morgagni-Aschoff's "intramural" form of calculus of the gallbladder, studies the anatomy, histology, pathology and pathogenic significance of 'Luschka's tubules' which have been considered the anatomic structure from which intramural calculus develops, and reports three cases of the "interstitial" form of calculus, that is, calculi formed in the tissural layers of the walls of the gallbladder not originated in the Luschka's tubules, as well as the results of the clinical, anatomic, histopathologic and histochemical studies performed in his cases. The condition was associated with lipoidosis and in one case, with a strawberry gallbladder and the classic form of intramural calculus. The mechanism of formation of the calculi is explained as follows. In one or more perivascular cells of the reticulo-endothelial system a process of primary infiltration with lipoids (cholesterol and its sterols), bilirubin and calcium occurs. The subsequent nuclear degeneration and structural destruction of the cells results in the liberation of moriform masses of lipoids, which accumulate in the tissural layers of the gallbladder. Owing to the mechanical and chemical stimulation of cholesterol the process is associated with an active and periodic proliferation of connective tissue cells with formation of giant plasmodial cells, which, because of the local and general factors, especially those related to the disturbances of the cholesterol metabolism, are in turn subjected to the same processes of lipid and pigmented infiltration, cellular degeneration and liberation of moriform masses, which add themselves to those previously stored in the parietal layers of the gallbladder. By this mechanism true calculi of cholesterol, mixed with calcium, are formed in the walls of the structure. The author compares and identifies the observations made in cases

of lipoidosis and of strawberry gallbladder with those observed in his cases of interstitial calculus. He comments on the modern views of the clinical and anatomopathologic differentiation between a gallbladder with lipoidosis and a strawberry gallbladder, two conditions which have been considered initial stages of lipid infiltration and which he considers two phases in the evolution of interstitial calculus. He emphasizes the practical and theoretical importance of his hypothesis on the existence and origin of the interstitial form of calculus as a form of equal importance with the classic intramural form, with which it may coexist in the same gallbladder without any mutual interdependence.

*Pancreatic Diastase During Pregnancy. V. Marzetti—p. 1651
Patrid Pneumothoracic Empyema and Secondary Myiasis. V. Maccone—p. 1656

Pancreatic Diastase During Pregnancy—Marzetti studied the pancreatic diastase of the blood of forty-five women in different stages of pregnancy, according to the method proposed by Katsch. The latter consists in placing 0.1 cc. of blood in 2 cc. of a 0.3 per cent solution of glycogen. The mixture is put in an incubator for two hours. The dextrose content is determined after removal of proteins. The blood sugar determination previously made on fasting and the individual reduction value of the glycogen solution are subtracted from the dextrose determination. This practical measure for the diastatic power of the blood is applicable to all blood sugar tests. The author found a marked increase of the pancreatic diastase in pregnancy. This he attributes to the hyperproduction of ferments through greater pancreatic action. This action is also believed to have been influenced by the mechanical factor of pregnancy and by the fetal pancreas through the mother. The author concludes that the method of Katsch is a valuable aid in determining the carbohydrate metabolism in pregnant women and, in an indirect way, in testing the hepatic function, which runs parallel to the pancreatic function.

Rudimentary Polyserositis and Its Sequels. H. Mayrhofer—p. 385

Atelectasis and Course of Pulmonary Tuberculosis—Coryllos found that atelectasis is not an occasional complication but a constant phenomenon in the course of pulmonary tuberculosis and that it plays an essential part in the course of the disease, particularly in the development of the tuberculous caverns and in the healing process. His observations lead to a new estimation of the significance of the collapse therapy. He compares a cavern in the presence of a pneumothorax with a bronchial fistula, the air content of which is never absorbed, because it is always refilled by the bronchial fistula. He further evaluates the significance of anaerobic conditions for the metabolism of the tubercle bacilli in the caverns. Then he discusses the relation between the oxygen deficiency and the development of connective tissue showing that pulmonary collapse and atelectasis favor the development of connective tissue in the healing process of tuberculous changes. He stresses the significance of immobilization in the treatment of tuberculous organs, for he is convinced that deficiency of oxygen and development of anaerobic conditions play an important part in the destruction of tubercle bacilli.

Mediastinal Lymph Nodes of Aged Persons—Arnstein shows that in aged persons the disorders that can be traced to tuberculous or anthracotic indurations or to softening of the mediastinal lymph nodes are extraordinarily manifold. The incidence of such disturbances is comparatively high. To the

usual diagnostic difficulties that are encountered in patients of the higher age groups are added those that are due to the type and localization of the primary disturbance. However, in the greatest majority of the cases it is possible to identify the disorder with considerable certainty, provided the details of the clinical aspects are given consideration. The leading symptoms are paralysis of the recurrent nerve, particularly of the left side, roentgenologic demonstration of an adhesion diverticulum or a traction diverticulum of the esophagus, coughing up of a blackish substance in the sputum, repeated attacks of pneumonia in the same portion of the lung or atypically localized, and usually circumscribed lobar tuberculous foci. The differential diagnosis is made difficult by various tuberculous and nontuberculous disorders and particularly by bronchial carcinoma, for the latter develops occasionally in aged persons. The treatment of the processes of induration and of softening and of their sequels in the mediastinal lymph nodes of the aged should be conservative. A more active treatment is advisable only in exceptional cases.

Genesis of Prostatic Hypertrophy—Reischauer emphasizes that an important factor in the histologic study of the genesis of prostatic hypertrophy is the use of special stains to bring out the elastic fibers. The so-called prostatic hypertrophy is not a compensatory regenerative process on the part of certain glandular elements. The new growth is formed by the proliferation of the mesenchymal tissue of the centrally located layer of muscle about the prostatic urethra. The new formation is capable of further growth even in the absence of the so-called preexisting or accessory prostatic glands frequently found in the fibromuscular ring of the prostatic portion of the urethra. The resulting tumor devoid of glandular elements, cannot, however be grossly distinguished from an 'adenomatous' hypertrophied prostate. These prostates, composed almost entirely of fibromuscular nodular masses, do not owe their character to the destruction of the glandular elements and their replacement by fibro-adenomatous tissue but are primarily devoid of glandular elements. The distribution of glandular elements in the new formation is confined to the junction of glandular epithelium with the localized proliferating fibromyomatous bundles of the urethral portion. The growth stimulus is imparted to the epithelium, if it exists at the junction, resulting in the formation of epithelial proliferations. These develop into individual nodules, which grow faster than those devoid of an epithelial covering. They dominate the picture and are referred to as fibro-adenomas. The same process may occur secondarily. The junction of epithelium with the spindle cell fibers may take place secondarily. The epithelium of the so called preexisting glands as well as of the urethra may respond to the growth stimulus imparted to it by the new connective tissue. The epithelium of the excretory ducts at the junction with the proliferating mesenchymal tissue may be stimulated to glandular proliferation in the same nodules. The author has frequently found this to be the case. Prostatic hypertrophy, therefore, is not to be regarded as a fibro-adenoma in the usual sense in which the epithelium is the sole proliferating element. The primary element is the centrally located prostatic musculature. The sprouting of the spindle-cell fibers may take place in the absence of glands in the median lobe of the prostate. The relationship to myomatosis of the uterus becomes more evident if the proliferation of the stroma is considered the cause of prostatic hypertrophy.

Significance of Mesenteriolitis in Appendicitis—Levin made a study of forty-one cases of acute appendicitis, forty-five cases of interval and eleven cases of so-called primary chronic appendicitis, with particular attention to the mesen-

terium of the appendix. He concludes that in every case of appendicitis there are definite inflammatory alterations in the mesenterium of the appendix. The extent of alterations in the mesenterium corresponds to the severity of the infectious process in the appendix. The following typical alterations were present in the mesenterium in the acute stage of appendicitis: edema, infiltration with polymorphonuclear leukocytes, acute lymphangitis with frequent thrombophlebitis, reaction on the part of the endothelium of the capillaries and the mesothelial cells, and a perivascular, perimural and, at times, endomural, leukocytic infiltration. The mesenterium exhibited in every case traces of the former inflammatory processes in the form of newly built connective tissue bands, of endovasculitis and perivasculitis, perineuritis and endoneuritis, accumulations of histiocytes and lymphoid cells and, at times, typical formation of lymphoid follicles. The histologic study of the mesenterium is of importance in the fixing of a pathologic diagnosis of appendicitis. The local as well as the reflex pains of appendicitis are caused by mesenteriolitis. The mesenterium acts as the first barrier to the infection spreading from the appendix. The symptomatology of acute and chronic appendicitis is expressed by pains originating in pathologic alterations in the mesenterium and the mesentery. Pain and local tenderness are not pathognomonic for appendicitis, since mesenteriolitis and mesenteritis, which cause them, may be produced by other disease processes in this locality. The local symptoms support rather than decide the diagnosis of appendicitis. Persistence of symptoms after the removal of an acutely inflamed appendix is due to the persisting mesenteriolitis and mesenteritis. Physical therapy is indicated in such cases. Theoretically one might urge an operation, aiming at the interruption of the impulses of pain by sectioning the ileocecal nerve. The possibility of the flaring up of a latent infection in the mesentery must not be lost sight of in operating in cases of interval appendicitis.

Is Diabetes Insipidus a Genitohypophyseal Disorder?—Lickint says that diabetes insipidus was formerly considered a hypophyseal disorder. In view of the relations between the anterior lobe of the hypophysis and the gonads and the fact that in other diseases of the hypophysis, such as acromegaly, gigantism, hypophyseal obesity, adiposogenital dystrophy and eunuchoid gigantism, there frequently exist disturbances of potency and other gonadal disorders, it is probable that at least the genuine form of diabetes insipidus is a genitohypophyseal and not primarily a hypophyseal disorder. He considered this the more probable after observations on twelve male patients with diabetes insipidus. A number of other reports call attention to the much higher incidence of diabetes insipidus in men than in women. He thinks that the male gonad plays an important part as an eliciting factor of diabetes insipidus. Six of ten patients observed by him had disturbances of potency before diabetes insipidus became manifest and these disturbances became more severe later. In this connection it is pointed out that the hypophysis has been known to increase in size following extirpation of the male gonads. Treatment with testicular preparations was tried in one of the author's cases, while in the others only hypophyseal preparations were employed. There was a favorable response to the testicular preparations. The author concludes that an exogenic nova, such as an infection or a trauma, may be the eliciting factor in so called symptomatic diabetes insipidus. However, a disturbance of the gonads is responsible in the genuine form, at least in some of the cases.

Ninhydrin Reaction of Serum for Diagnosis of Cancer—Lehmann-Facius and Witting point out that Abderhalden introduced a ninhydrin reaction in 1927, which subsequently was modified by other investigators, and describe their own technic of the ninhydrin reaction as follows. Two cubic centimeters of active serum from a patient together with 0.2 cc. of fresh normal guinea-pig serum that had been diluted with an equal amount of physiologic solution of sodium chloride is mixed in sterile test tubes. The tubes are plugged with sterile cotton and placed in an incubator (37 C.) for from eighteen to twenty-four hours. Then 5 cc. of pure 96 per cent alcohol is added and the tubes are boiled in the water bath until the alcohol has boiled up once. This is followed by filtration into new tubes through a Schleicher-Schüll filter No. 595. To this alcohol filtrate is added 0.1 cc. of a 1 per cent alcoholic solution of ninhydrin. A glass rod is placed in the tube and the contents of the tube are boiled for ninety seconds under constant movement over the Bunsen burner. In a control series 0.2 cc. of the patient's serum is mixed with 0.2 cc. of physiologic solution of sodium chloride, and 0.2 cc. of twice diluted guinea-pig serum is mixed with 0.2 cc. of physiologic solution of sodium chloride. Specimens of serum of which the alcoholic filtrate produces with ninhydrin a noticeable blue coloration may be considered positive, while the controls remain either water clear or show a slight yellow. It has been observed that particularly in the positive tests the alcohol filtrate boils down considerably. In that case it must be filled up to the original amount by the addition of alcohol. The reading should always be taken against a white paper background. According to the intensity of the blue coloration various degrees of reactions may be distinguished. The blood specimen with which the reaction is made should be withdrawn in the morning while the patient is still fasting. The serum should be poured off and centrifuged soon after it has become separated from the clot so as to prevent the passage of hemoglobin into the serum. The test should be begun on the same day on which the blood is withdrawn. The same rules apply to the guinea-pig serum. The examination of 415 serums revealed that the ninhydrin method indicates the presence of carcinoma in about 70 per cent of the cases, while 90 per cent of the patients who are free from it give negative reactions. The ninhydrin method is based on the fact that the serum protein of patients with cancer is attacked by the antibodies contained in normal serum (guinea-pig serum), in this process alcohol soluble cleavage products are produced which can be demonstrated by means of ninhydrin.

Behavior of Eosinophils in Itching Skin Diseases—To determine whether there are connections between the behavior of the eosinophils of the blood and the itching in certain skin diseases Salisico examined patients with various skin diseases. In patients with eczema, he generally observed an increase but the eosinophil count was never high and there was no parallelism between itching and eosinophilia. Cases of pruritus showed greater uniformity, the eosinophil count being on the upper limit of the physiologic values. The blood picture in lichen Vidal disseminatus showed a pronounced eosinophilia but there was no relationship between the degree of eosinophilia and the intensity of the itching. In cases of scabies the behavior of the eosinophilia was not uniform, but the values were generally rather high. In urticaria developing after ingestion of strawberries, the eosinophils were considerably increased. After three days the values returned to normal and there was parallelism between the itching and the increase and decrease in the number of eosinophils. The eosinophil values in pyoderma remained within normal limits. In a case of dermatitis herpetiformis Dühring fluctuating values were noticed but there was no accumulation of eosinophils in the itching skin areas. In

pemphigus vulgaris there was only a slight increase in eosinophilia, however, large numbers of eosinophils were detected in the blisters. The author thinks that in dermatoses eosinophilia and itching seem to be connected in that both are caused by an alteration of the skin. Itching seems to develop in response to the slightest, not yet visible, tissue infiltration, whereas pathologic changes in the number of eosinophils seems to develop only in response to graver disorders (disintegration of epithelia, liberation of parenteral proteins that exert a toxic influence). Eosinophilia and itching do not have to run parallel but may do so in cases in which irritation of the nervous system and of the blood forming apparatus are equally severe. The author further points out that, if the disease process persists for longer periods, well formed eosinophils are replaced by those that show signs of degeneration. In severe disorders that terminate fatally, a transformation of an eosinophilic blood picture into an aneosinophilic one seems to take place.

 Subcutaneous Rupture of Biceps and Its Treatment. H. Hanke—p. 807

Effect of Loss of Chlorides on Intestinal Activity—Eitel and Loeser removed pieces of small intestine of from 15 to 3 cm. in length from guinea-pigs and rabbits and placed them in a modified Locke's solution. Physostigmine or prostigmine in a dilution of 1:20,000,000 was added for its peristaltic effect. The peristaltic movements of the intestinal segments were recorded by means of a kymograph. Three modified solutions were likewise experimented with in which the sodium chloride content was raised 50, 75 and 100 per cent, respectively. The behavior of the intestine was the same when it was placed in Locke's solution that did not contain sodium chloride, and when to the same solution sodium sulphate, sodium nitrate or sodium acetate was added. These solutions failed to influence the peristaltic effect of physostigmine. When the pieces were placed in Locke's solution that was not deprived of its sodium chloride, the normal peristaltic movements developed after a few minutes. The authors conclude that a certain amount of chlorine ions is essential in order to provoke the peristaltic effect of certain medicaments. To test their contention *in vivo*, the authors placed guinea-pigs on a diet capable of reducing the chloride content of the blood. This consisted of corn washed in distilled water. They were given abundant lime water. Theobromine sodiosalicylate, 1 Gm., was given daily. When the chloride reduction reached the point of producing convulsions, the animal was killed and segments of the intestine were removed. These segments, when placed in Locke's solution with a reduced chloride content, failed to show spontaneous active peristalsis characteristic of the intestine of a guinea-pig. These experiments demonstrate the effect of hypochloremia on intestinal peristalsis. They likewise explain the therapeutic effect of administration of hypertonic solutions of sodium chloride in ileus as recommended by Orr and Haden.

Posttraumatic Dry Knee Joint.—Jirasek defines a dry knee as a condition of the knee joint in which, in the course of an operation undertaken because of symptoms following an injury, no fluid or only a slight amount is found. He observed this condition in twenty-four cases. The subjective symptoms were diffuse pains in the knee, limited and painful movements and uncertainty of the knee. Among the objective symptoms were noted limitation of flexion, less frequently of extension and, in most cases, limping. The extension symptom as well as tenderness of the inner aspect of the joint were frequent. Atrophy of the quadriceps was commonly observed. Acoustic phenomena were present in half of the cases. In sixteen no fluid was observed in the joint during the operation, while in eight only traces were observed. It is uncertain whether this condition constitutes an independent nosologic entity, a functional state or a definite disturbance of the synovial membranes. The remote results and the proper treatment of these cases are as uncertain as the cause itself.

Vitamin A and Serum Cholesterol—Lasch approached the problem of the action of vitamin A on the cholesterol content of the serum from two points of view. He studied (1) whether it is possible to increase the serum cholesterol of human subjects just as has been done in animals and (2) whether a regulating action of the liver on the cholesterol metabolism can be found by the determination of the different cholesterol fractions. He observed that if from 40,000 to 80,000 rat units of vitamin A is administered three times daily to human subjects, an increase in the cholesterol content of the serum becomes manifest in from five to ten days. The increment is due primarily to an increase of the cholesterol esters, and this indicates a direct action on the regulatory function exerted by the liver on the cholesterol metabolism.

Antianemic Liver Extract in Toxic Anemia—Paschkis and Taylor point out that pernicious anemia is classified with the hemolytic anemias and that for this reason it was logical to examine the action of antianemic liver extract on experimental hemolytic anemias. The experimental anemia that has been examined most frequently is the one produced by phenylhydrazine. Some investigators have maintained that liver extract has no influence on this type of anemia, while others have stated that liver extract would cure this type of anemia. A protective action of liver extract against poisoning with phenylhydrazine appeared dubious to the authors, because the anemia induced by means of phenylhydrazine differs essentially from pernicious anemia. They decided to duplicate the experiments of the investigators, who asserted that they observed a protective action of liver extract against phenylhydrazine poisoning. The authors made their experiments on rabbits instead of on dogs and found that liver extract never exerts a protective action against a subsequent phenylhydrazine poisoning. Then they studied saponin anemia and found that treatment with liver extract prevents saponin anemia in rabbits. They discuss the significance of this observation for the hypothesis of the action of liver therapy and assume that liver extract counteracts a toxic influence in pernicious anemia.

Thyroxine and Blood Coagulation Prophylaxis of Thrombosis—Kausch describes observations on the coagulation of the blood following intravenous administration of thyroxine and also after the oral administration of another thyroid extract. He found that several days of administration of thyroid extracts produced a retardation of the coagulation of the blood in the minority of the cases and only in a slight degree. However, he believes that in spite of this the medication with thyroid extract is helpful in the prophylaxis of the postoperative thromboses and embolisms, for the thyroid extract stimulates the circulation and the metabolism and incites the patients to greater mobility.

Management of Delivery Without Protection of Perineum—Fraymann designates as "protection of the perineum" all the manipulations employed in facilitating the passage of the fetal head through the vulva. He compared deliveries in which the perineum was given protection (2,000 cases) with

those in which this was not done (762 cases). He found that in primiparas the perineal tears were by 7 per cent more frequent in the absence of perineal protection than with it; in multiparas the incidence was higher by 61 per cent. The smallest fetus causing a rupture in a primipara with perineal protection weighed 2,000 Gm. and in a multipara 2,220 Gm. The largest fetus that did not cause a tear in a primipara without perineal protection weighed 4,450 Gm. The puerperium takes a more favorable course without perineal protection than with it. A comparison of the two groups (without and with perineal protection) without ruptures shows that among those with perineal protection the number developing fever is much higher. Consequently, those in whom the perineum was protected have to stay at the hospital somewhat longer. Traumas of the fetus were 18 times more frequent in cases with perineal protection than in those without it, and asphyxia of the infants was 7.3 times more frequent. The author maintains that without perineal protection severe asphyxia or even death of the fetus is almost never observed. In managing a delivery without perineal protection, the respiration of the parturient woman must be given attention while the head passes the vulva, so that the passage takes place outside of the expulsive labor pains.

*Treatment of Sciatica with Histamine Iontophoresis A Dzsinich—p 1693
Influence of Calcium Salt of Dioxypionic Acid and of Calcium Gluconate on Calcium Content of Serum in Various Modes of Administration K. Durr—p 1694

Treatment of Sciatica with Histamine Iontophoresis—Dzsinich points out that many investigators believe that circulatory disturbances play a part in the pathogenesis of sciatica. It is believed that a local vascular spasm retards the circulation, and this in turn leads to an accumulation of metabolic waste products. The ischemia and the waste matters irritate the nerve and the surrounding muscles, and painful spasms are the result. On the basis of this theory, Deutsch developed the treatment with histamine iontophoresis, for, if histamine is introduced in this manner, the capillaries become dilated, their permeability increases and the arterioles become dilated by reflex action. The author decided to try this treatment in patients with true sciatica. A special type of foil was attached to the anode, was dampened and was then applied. The foil was applied at four different sites, first on the gluteal muscles, then on the popliteal fossa, then on the ankle and finally on the antagonistic muscles of the extensor side of the thigh. The negative pole, in the form of a large, flat electrode, was applied to the thorax. The author considers it advisable to employ a battery current. He began the treatment with from 6 to 8 milliamperes, applying the electrode for from three to four minutes to the sites mentioned. The treatment was repeated daily and the strength of the current was gradually increased. Of the thirteen patients treated in this manner, five were completely cured, five showed great improvement, two were slightly improved and one remained unchanged. Chronic cases were less amenable to treatment than the recent cases. The author concludes that histamine iontophoresis is as effective as other physical methods and stresses that the treatment is simple, short and not unpleasant.

Sitz Baths in Gynecology H Erner—p 1727

Prophylaxis of Diphtheria by Combined Method—The increasing incidence of diphtheria induced Kauert to protect the children newly admitted to his sanatorium by means of passive immunization with diphtheria beef serum. Since the protective

action of this passive immunization begins to subside after four weeks, the author decided to add to this procedure the active immunization by diphtheria anatoxin, which becomes effective after four weeks. The result of this combined immunization surpassed all expectations, for the diphtheria epidemic ceased at once in the children's sanatorium.

Dry Blood Test for Syphilis—Dahr describes further experiences with Chediak's method. His first report in the *Deutsche medizinische Wochenschrift* (60 94 [Jan. 19] 1934, abstr. THE JOURNAL, March 31, 1934, p 1113) was based on experiences on 600 specimens. Now his observations cover 1,000 specimens and he has slightly modified his technic. Whereas in his first experiments he followed Chediak's suggestion and used the "original extract" of the Meinicke clarification reaction I he now employs the "original standard extract" of the Meinicke clarification reaction II. This is advantageous because, if the first extract is used the blood as well as the extract must be diluted with a solution containing 35 per cent of sodium chloride and 0.03 per cent of sodium carbonate and this solution must always be freshly prepared, while if the second extract is employed it is sufficient to use the 35 per cent sodium chloride solution without the addition and this solution does not have to be freshly prepared each time. Moreover, the use of the second extract improves the reliability of the test. The author reiterates the advantages of the dry blood test, stressing particularly its reliability, rapidity, simplicity and inexpensiveness. However he admits that for the clarification of difficult diagnostic problems the test alone is not adequate but should be done together with several other serologic tests.

Strahlentherapie, Berlin

- Small Field Roentgen Therapy of Deep Lying Tumors A. Kukowka—p 312

Persistent Cutaneous Carcinomas and Their Cure—Hintze designates as "persistent" those cases of cutaneous carcinoma which, more than five years after the first treatment (surgery or irradiation), are not free from symptoms, or, after having been free for some time are again in need of treatment. He describes observations on seventy-one persistent cutaneous carcinomas, of which thirty-nine had first been treated surgically and thirty-two irradiated. The majority of the carcinomas (sixty-two cases) involved the face. Of four cases in which the first as well as all successive treatments had been surgical, not a single case was cured. Of thirty-five patients who had first received surgical treatment but who later had been irradiated, nineteen were cured by irradiation in the author's clinic. Of seventeen patients whose first treatment had been irradiation (in other clinics) one case was cured by an operation, while four were cured by irradiation in the author's clinic. In nine of the fifteen patients who had been treated first with radiation in the author's clinic, multiplicity was the cause of the persistence, while in six cases the primary focus persisted or relapsed. Of the group who had multiple tumors eight are now cured, and of the relapsing group three were cured. Two of the three relapsing cases that were not cured had been treated with repeated small doses (old method) in one the doses had been of medium size, and in none had large doses been given during the first treatment. The author maintains that persistence in case of cutaneous carcinoma—aside from multiple foci—is the result of inadequate primary treatment.

Extremely Hard Roentgen Rays in Treatment of Carcinoma—Von Schubert states that the women's clinic of the Charité in Berlin has had the use of a gamma volt apparatus

for the last three years and thinks that it is now time to give a preliminary report about the results obtained with extremely high tension in the treatment of carcinoma. Following a recapitulation of observations on animals and plants, he states that experiments on a paraffin phantom of dimensions corresponding to those of the human body revealed that in case of a tension of 575 kilovolts, of a filter of 3 mm of copper and 3 mm of aluminum, of a field of incidence of 19 by 19 sq cm., and of a focus distance from the surface of 100 cm., 65 per cent of the surface dose was demonstrable at a depth of 10 cm. Measurements in the vagina of a patient indicated that about 67 per cent of the administered dose was effective in the pelvis. The author discusses the number, size and arrangement of the fields, the dose, the intervals between the irradiations, the tolerance of the skin, serial and massive irradiations, the addition of radium rays, the general reactions, the blood picture and the effect on the tumor. Then, after describing the material, he points out that the severest cases had been selected for this treatment. Nevertheless, in carcinoma of the uterine cervix several permanent cures were obtained, and in some other localizations, such as in the esophagus, at least a temporary improvement was produced. In several cases of vaginal carcinoma the results seemed likewise favorable. However, the observations so far do not permit the conclusion that the results obtained with this method surpass those of other methods. But it can be asserted that the normal tissues tolerate this type of irradiation relatively well. Moreover, rather large doses may be applied within a comparatively short period without causing severe cutaneous and general reactions. Thus, if cure should depend on the size of the dose, this method would prove advantageous.

Wiener klinische Wochenschrift, Vienna

Iodine Content of Blood in Circulatory Disease—Kisch observed that the iodine content of the blood of patients with circulatory insufficiency has normal values even if there exists a considerable increase in the basal metabolism. The heightened basal metabolic rate frequently observed in patients with heart disease and with cardiac insufficiency, therefore, cannot be ascribed to an excessive production of hormones by the thyroid. The iodine content of the blood may fluctuate slightly when the circulatory disturbance improves or when it becomes exacerbated. However, these fluctuations always remain within normal limits and they show no relationship to the behavior of the basal metabolism. In a number of obscure circulatory disturbances in which there existed changes such as increased basal metabolism, tachycardia, slight dilatation of the heart and swelling of the thyroid but in which exophthalmos was absent, the iodine content of the blood was normal, so that it would not be justifiable to assume the existence of hyperthyroidism. In patients with goiter, who had an increased iodine content of the blood, there was always exophthalmos and profuse blood perfusion of the skin. The question whether the increase in the iodine content of the blood is absent also in cases of inactive exophthalmic goiter, in which the basal metabolic rate is increased, may be answered in the affirmative.

Immunization Experiments with Gonadotropic Hormones—Ehrlich attempted to immunize rabbits and sheep by repeated intravenous injections with a gonadotropic hormone preparation. He performed these experiments not only because of theoretical interest but also because he thought it possible to arrive at a method for the diagnosis of pregnancy. He gives tabular reports of various tests and states in the conclusion that by repeated intravenous injections it was possible

to produce in rabbits and sheep specific antibodies against the hormone of the anterior lobe of the hypophysis. It proved possible by means of serologic methods to effect a sharp differentiation between two hormones of the anterior hypophysis, the gonadotropic and the thyrotropic. He admits, however, that in the present status of experiments it is not yet possible to employ the immune serums for the early diagnosis of pregnancy. He thinks that a considerable amount of experimentation will have to be done before the problem has been completely clarified.

Eczema of Pregnancy Cured by Removal of Focus of Infection G. van Bud—p. 2619

Diagnosis of Tubal Pregnancy—Among seventy-eight cases of tubal pregnancy, Fink states that forty were referred to his clinic with an erroneous diagnosis. Some cases were wrongly diagnosed as appendicitis, cholecystitis and peritonitis. These are the least grave mistakes, since surgery is resorted to at once and the condition is clarified by operation. The incorrect diagnoses are more reprehensible if the examination and the taking of the anamnesis have been inadequate. Under those conditions, tubal pregnancies have been diagnosed as displacement or prolapse of the uterus with tumor or as a cyst. In another group of cases curettage had been done. The author admits that the cases presenting typical symptoms were hardly ever wrongly diagnosed, but he points out that the atypical cases seem to be more frequent. He considers it a mistake in clinical instruction to overstress the typical symptoms of tubal pregnancy. The atypical cases should also be given attention.

Resection of Superior Hypogastric Plexus in Pelvic Pain—Wetherell suggests the resection of the superior hypogastric plexus in cases of severe pelvic pain. He obtained relief in cases of dysmenorrhea, in severe pain of advanced uterine carcinoma and in cases in which the usual gynecologic operations and the therapeutic measures failed. The necessity of diagnosing and treating pathologic conditions of the pelvis that are discovered in the course of this operation brings it into the sphere of the gynecologist. The author points out that it may become necessary to resort to ganglionectomy and to ramisection, and in some instances chordotomy may even be required. The latter intervention, however, should be done by a neurologic surgeon. The author describes the topographic conditions of the hypogastric plexus and the method of resection and calls attention to certain dangers that must be avoided. He stresses the necessity of a careful anamnesis to bring out that the pain actually involves the pelvis.

Reaction of Uterus to Solution of Pituitary—Tachezy states that according to Knaus the uterus of animals as well as of human beings ceases to react to solution of pituitary with an increase in the tone as soon as the secretion of the corpus luteum becomes active. Knaus had observed that in women with a cycle of twenty-eight days this action of the corpus luteum is evident from the sixteenth day to the penultimate day of the cycle. Since the influence of the corpus

luteum commences from twenty-four to forty-eight hours after ovulation, Knaus reasoned that in a cycle of twenty-eight days ovulation takes place between the fourteenth and sixteenth day. The author cites several other investigators who studied the same problem and shows that one agreed with Knaus while two others contradicted him. Then he describes his own studies and in summarizing them he states that he was unable to corroborate the inhibiting influence of the corpus luteum hormone on the reaction of the uterine musculature to solution of pituitary. In the cases examined by him, the reaction to solution of pituitary was most typical during the second half of the cycle, that is, during the time the hormone of the corpus luteum supposedly exerts its strongest action. In five pregnant women (between the second and fifth months) he obtained always positive reactions. On the basis of these tests he concludes that the ovulation term cannot be determined in the manner in which this is done by Knaus.

*Vascular Pathology of Epidemic Cerebrospinal Meningitis A. I. Geymanovich and N. I. Golik—p. 455

Symptoms and Prophylaxis of Ergotism—Gaysinovich and his co-workers divide ergot poisoning, resulting from ingestion of bread contaminated with ergot, into three forms: (1) the spasmodic, (2) the gangrenous and (3) the mixed. They have noted in the gangrenous form a stage that they consider pregangrenous and capable of regression without reaching the stage of gangrene. The spasmodic form was the most frequent. Symptoms of intoxication may manifest themselves between the first and the twentieth day after the ingestion of contaminated bread. They consist of vertigo, general weakness, somnolence, paresthesias and gastro-intestinal disturbances. After two or three days there appear intensely painful muscle cramps of the flexor groups of hands and feet. Occasionally there may be psychic symptoms such as restlessness, excitement and increased motor activity. Epileptiform fits were observed. The gastro-intestinal disturbances consisted of vomiting, profuse diarrhea and abdominal pains. The blood pressure was raised and the blood picture showed a pronounced eosinophilia of from 5 to 19 per cent. There were atypical cases showing only severe gastro-enteritis and no spasmodic manifestations. The authors call attention to a rare form that resembles closely tabes dorsalis. Gangrene of the terminal areas of extremities manifests itself from ten to fifteen days after the onset of general symptoms of poisoning. The gangrene is preceded by severe continuous pains, coolness and bluish discoloration of the extremities. The authors administered intravenously from 15 to 20 cc. of a 3 per cent solution of magnesium sulphate daily and felt that the results were superior to those obtained from exhibition of the usual narcotics and bromides. In the pregangrenous form, 1 cc. of 1 per cent solution of pilocarpine was administered daily because of its dilating effect on the blood vessels.

Vascular Pathology of Epidemic Cerebrospinal Meningitis—Geymanovich and Golik found pronounced alterations in the blood vessels not only of the meninges but of the brain tissue as well in cases of epidemic cerebrospinal meningitis. They have observed in the subacute cases in children a well developed endarteritis, hyaline degeneration of arteries and panphlebitis in the substance of the brain tissue. The meningeal vessels were the seat of endarteritis with hyaline degeneration. Pronounced endarteritis was not observed in young adults, in whom the predominating lesion was hyaline degeneration with thrombosis. In patients of advanced age they found hyaline degeneration of blood vessels with lymphoid infiltration and necroses about the vessels and scattered minute hemorrhages. The postmeningitic headaches are probably the

result of these vascular alterations. The possibility of vascular changes in postmeningitic cases must therefore always be kept in mind.

Diagnosis of Chorionepithelioma—Gröné calls attention to the difficulty of diagnosing certain cases of chorionepithelioma and shows that the Aschheim-Zondek pregnancy reaction is a valuable aid in the diagnosis. He reports the history of a woman, aged 28, who developed a hydatid mole immediately following the first pregnancy. The mole was expelled and two days later the remnants were removed with a blunt curet. Immediately thereafter, lutein cysts, each the size of a fist, appeared on both sides of the uterus. A month later they had almost completely disappeared, but the uterus was enlarged and a sanguinolent discharge persisted. On the basis of the microscopic examination of the material removed by curettage, a chorionepithelioma was suspected. The Aschheim-Zondek test proved strongly positive, but titration disclosed only 28,000 mouse units of hormone in each liter of urine. An expectant treatment was decided on, and after another two months the condition was practically unchanged. The uterus was perhaps somewhat larger, but it could be moved. During this time there occurred no profuse hemorrhages but there was constantly a slightly bloody discharge. Repeated curettage revealed the same results. The Aschheim-Zondek reaction remained strongly positive, but the urine contained less than 28,000 mouse units of hormone per liter. Inoculation of curettage material into mice gave positive reactions. Following the total extirpation of uterus and adnexa, three months after the expulsion of the mole a typical chorionepithelioma was detected on the anterior wall of the uterus. Two weeks after this operation, the Aschheim-Zondek reaction was negative. Before discharge from the hospital, the patient was given six high voltage roentgen treatments. Six months later the Aschheim-Zondek reaction was still negative and the patient had gained weight. The author reiterates the value of the Aschheim-Zondek test, describes the titration method and the examination of tissues, and stresses the hormone origin of the lutein cysts. In discussing the significance of the negative outcome of the Aschheim-Zondek reaction, the author describes a case in which chorionepithelioma was suspected on the basis of the microscopic observations. Operation disclosed a myomatous thickening of the uterine wall with a placental remnant. The author does not believe that it is possible to make a general rule for cases in which the hormone and histologic symptoms point in different directions. The strength of the hormone titer, the age of the patient and her desire to preserve the child-bearing capacity must be weighed in the different cases.

Plastic Operation for Vaginal Defect—Nielsen reports the successful plastic formation of a vagina according to the method of Kirschner-Wagner. The advantage of this operation in comparison with those previously employed is that, by a comparatively simple intervention a vaginal tube is created, which is covered with squamous epithelium and, except for the lighter color of the mucous membrane, closely resembles the natural vagina. The principle of the operation is that from an incision behind the small fovea, which in congenital vaginal defect is to be found behind the urethral orifice, the surgeon penetrates bluntly to the peritoneum in the fossa of Douglas, and that when the canal so formed has been dilated to fully

two fingerbreadths, an epithelium-clad prosthesis of rubber sponge is inserted. The after-treatment, which begins with the removal of the prosthesis from ten to fourteen days after the operation and consists in daily dilation of the canal formed, is an important part of the procedure.

Extraperitoneal Endometriosis—Nielsen reports two cases of external extraperitoneal endometriosis, one vaginal and one in the round ligament. Of the theories that have been advanced so far (the embryonal, the sero-epithelial, the metastatic and the implantation theory) the last mentioned must be regarded as accounting most convincingly for the genesis of endometriosis. The uterine genesis has been proved for both internal and peritoneal endometriosis. As regards the vaginal case, a lesion of the vagina had occurred two or three months before the symptoms began to show, and it is probable that an implantation of endometrial particles into the wound had taken place during the subsequent menstruation. In regard to the case of endometriosis in the round ligament, it must be assumed that an implantation of endometrial particles had taken place in a preexisting vaginal process and that the endometriosis had spread from there to the round ligament and become established there while disappearing from the serous surface.

- Fractures of Spine and Resulting Invalidity N. Paus—p. 1298
- *Hormone Investigations in Pernicious Vomiting of Pregnancy H. Anker and P. Laland—p. 1324

Two-Stage Transvesical Prostatectomy—In Grön and Mikkelsen's material from 1925 to 1932, suprapubic prostatectomy was done in ninety-one cases of prostatic hypertrophy and eight of prostatic cancer. The average age in the first group was 69.33, four patients were more than 81. The gravest complication after prostatectomy was hemorrhage, and, after cystostomy uremia. Seven out of ninety-eight cases of hypertrophy ended fatally after the first stage operation, and seven of the ninety-one, or 7.7 per cent, after the second stage, giving a total mortality rate of 14.3 per cent. The later fate of seventy-nine of these patients is known: fifty-four are living and twenty-five have died (two as a result of the prostatectomy, twenty-three from intercurrent disease). Of the eight patients suffering from cancer, one died after operation, of the seven, two are living. The authors found that the majority of the patients were well after the prostatectomy, capable of work according to their ages, and micturating normally. Later, cancerous development was observed in two cases of hypertrophy. Prostatectomy is considered the normal method in the treatment of hypertrophy. The indications are wide. When residual urine cannot be eliminated by catheter treatment for a short time, prostatectomy should be performed. Contraindications are renal insufficiency, grave infection of the urinary tract, senile dementia, myocarditis, coronary sclerosis and fatty heart. Advanced age is not in itself a contraindication, arteriosclerosis and hypertension are only a relative contraindication. Both cystostomy and prostatectomy call for preoperative treatment. Vasectomy should be done in prophylaxis. The endovesical resection method should until further notice be reserved for the experienced urologist. The possibility of cancerous development in an adenoma must be borne in mind in every case of prostatic hypertrophy. The prognosis for a clinically undemonstrable cancer in an adenoma is relatively good on enucleation.

Hormone Investigations in Pernicious Vomiting of Pregnancy—In three of eight patients afflicted with vomiting or pernicious vomiting, Anker and Laland found subnormal values of the anterior pituitary-like principle in the urine, these values in the serum were hypernormal in all cases. In the six patients in whom analyses of the anterior pituitary-like principle were continued during rest in bed and abundant administration of fluids, vomiting ceased simultaneously with the rise in the content of the anterior pituitary-like principle of the urine and the reduction of its content in the serum. Control analyses in pregnant women without vomiting showed normal values of anterior pituitary-like principle in the urine and the serum.

PAIN IN BENIGN ULCERS OF THE ESOPHAGUS, STOMACH AND SMALL INTESTINE

ANDREW B. RIVERS, M.D.
ROCHESTER, MINN.

With the possible exception of some esophageal ulcers, this study deals almost wholly with the experiences of patients harboring peptic ulcers. The symptoms commonly accepted as being diagnostic of peptic ulcer may be experienced by patients who do not have ulcer, and certain intrinsic gastro-intestinal lesions, such as benign tumor or carcinoma, occasionally produce symptoms clinically indistinguishable from peptic lesions. On the other hand, extensive or subacute perforating peptic lesions have often been observed among patients whose histories had lost to an appreciable degree the symptoms previously so characteristic for peptic ulceration.

Although there is a fairly consistent reduplication of characteristics in the syndrome of peptic ulcer, there is nevertheless much variability in the symptoms. This variability does not necessarily represent individual responses to the same morbid process, although changes in symptoms can often be noted in the same patients at different stages of the life cycle of the disease. This paper is concerned with the study of these mutations in order to ascertain whether certain pathologic complications consistently produce a similar behavior of the syndrome experienced by these patients.

It seemed reasonable that, when peptic ulcer passed through the various stages of its life cycle and invaded different depths of the tissues into which it burrowed, it might be expected to produce some definite changes in symptoms, as neighboring organs are invaded and as normal physiologic processes become increasingly disturbed, symptoms might well be assumed to arise which would substitute for or complicate the symptoms included in the original syndrome. Therefore ulcers in different portions of the gastro-intestinal tract were selected for study, the different states of pathologic development were ascertained by direct inspection of tissues and the various pathologic processes were correlated with the symptoms that were actually being produced at the time of laparotomy. By comparing a sufficient number of such lesions with the symptoms that were produced, it was believed that a type of serial section picture could be built up which would permit correlation of the varying changes in the histopathologic life cycle of peptic ulcer with the changing painful experiences noticed by patients harboring such lesions.

From the Division of Medicine, the Mayo Clinic.
Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

The usefulness of having accurate information regarding the actually existing pathologic conditions of the lesions under consideration is readily apparent.

By studying with sufficient thoroughness the exact situation of the pain and the course over which it is projected as well as the behavior of symptoms caused by lesions in varying situations and at varying depths of tissue, certain information may become available by which the anatomic and physiologic problems of abdominal pain and its pathways can be better understood.

PATHWAYS AND MECHANICS OF PAIN

Painful impulses arising from peptic ulcers may originate in the wall of the gastro-intestinal tract, course along over sensory bundles in the sheaths of the splanchnic nerves, cross over through the white rami communicantes of the thoracic nerves along the posterior roots, and thus enter the posterior horn of the spinal cord. Pain also may be conducted to the spinal cord over the sensitive cerebrospinal somatic nerves, twigs of which supply the parietal peritoneum and the mesentery. The vagus nerves carry some sensory fibers, but these are probably not very important in telegraphing to the brain painful impulses arising from peptic ulcers.

There are several other pathways by which painful impulses caused by peptic ulcers can leave the abdomen, such as through the ganglionated sympathetic chain or by way of the aortic plexuses, and thence through the rami communicantes to the spinal cord. Furthermore, if these lesions are situated high in the gastro-intestinal tract, the phrenic pathways may be utilized.

Difficulty at once arises, however, when an attempt is made to explain the origin of pain from viscera which ordinarily seem practically insensitive to the stimuli that experience has taught would produce pain on body surfaces. Lennander¹ attempted an explanation of this paradox by suggesting that painful impulses from diseased viscera reached the patient's consciousness through the medium of the parietal peritoneum and its subserous layer over the cerebrospinal sensory nerves. Ross² suggested that internal organs gave rise to two kinds of pain: true splanchnic pain, which was felt in the organ from which the afferent impulse arose, and an associated somatic pain, which, he believed, was felt in the cerebrospinal nerves of the body wall which are connected with the same segments of the spinal cord as the affected splanchnic nerve.

Mackenzie,³ accepting entirely Ross's hypothesis regarding referred somatic pain, denied the possibility

J.* 1: 1449-1454 (June 23) 1906. II. The Mechanism by Which Visceral Pain is Produced. *ibid.* 1: 1523-1528 (June 30) 1906.

that the splanchnic nerves could transmit impulses from the viscera interpreted by the brain as pain. Instead he suggested that the viscus sends forth a stimulus over the splanchnic afferent fibers into the posterior horn. There it sets up an area of increased irritability, producing hyperalgesia in the skin of the abdominal wall supplied by the cerebrospinal sensory nerves that enter the affected segment of the cord. This he called a viscerosensory reflex. He stated that an increased stimulus reaching the spinal cord in this way sometimes spreads to the anterior horn cells affecting a motor center, causing contraction of skeletal muscle in the area receiving

Fig 1—Ulcers of the esophagus. Left origin of pain. Right radiation of pain. In the charts each dot indicates the point at which each patient felt the maximal distress. Arrows indicate regions to which pain was projected, the depth of shading indicates relative frequency of pain shifts.

its nerve supply from the same spinal segment. This he described as the visceromotor reflex. In this way he attempted to explain rigidity overlying a painful abdominal lesion.

Hurst⁴ later pointed out that it should not necessarily be assumed that the viscera were insensitive because certain stimuli applied there were not interpreted as pain. He suggested that it was merely a matter of applying an adequate stimulus to the wall and

Fig 2—Left nonperforating gastric ulcers including subacute ulcers. Right perforating gastric ulcers not including perforation to liver. The only instance of shift of pain to the right in this group occurred in cases in which the perforation was to the pancreas.

argued that increased tension on the muscular wall of these organs can produce true visceral pain. He expressed the belief that abdominal tenderness associated with ulcer is either a "visceral" tenderness or a "reflex" tenderness. He suggested also that subserous connective tissue in a viscus is sensitive to pressure when inflamed, this he calls visceral tenderness. Reflex tenderness, he stated, is produced by impulses from the ulcer traveling over the afferent sympathetic fibers into

the spinal cord, rendering the segments to which they run abnormally sensitive. Local stimulation of the sensory fibers in the skin, subcutaneous tissues and skeletal muscles supplied by the same spinal segment as those of the organ in which the abnormal afferent stimuli originate give rise to discomfort or pain when under ordinary conditions no unpleasant sensation would have arisen from such stimulation.

Morley⁵ expressed the opinion that true visceral pain exists, but he suggested that tenderness and rigidity in the abdominal wall are entirely referred from the sensitive cerebrospinal nerves of the parietal peritoneum.

Palmer⁶ believes that hydrochloric acid plays a definite part in the production of the pain of peptic ulceration. By introducing 0.5 per cent hydrochloric acid into the stomach of the patients with peptic ulcer, he could produce pain consistently so long as the experiment was carried on during the period in which the ulcer was active. Mann and Bollman⁷ expressed the belief that the repeated introduction of 0.5 per cent hydrochloric acid into the stomach, at frequent regular intervals, will eventually produce severe pain. Hurst⁴ suggests that hydrochloric acid acts as a stimulus that ultimately raises the tension of muscular fibers in the coat of the viscus, thus causing pain. Kinsella⁸ believes that the pain of peptic ulcer is caused by local pressure on

the splanchnic nerves by the inflammatory reactions incidental to the ulcerating process. Wilson⁹ is of the opinion that relaxation of the duodenum when the food enters causes relief of pain.

MATERIAL FOR STUDY

Only those cases were accepted for study in which direct inspection of tissues was obtained and in which the history included exact information regarding the syndrome under consideration. These cases are summarized in the accompanying table.

An inquiry was made as to the situation of the lesion and as to the duration and character of the pain, its time of onset, mode of relief, and whether there were any appreciable differences in the general characteristics over the entire life cycle of the lesion under consideration. An effort was made to ascertain the location not only of the more recent areas of pain but also of those experienced since the origin of the syndrome attributed to the patient's present illness. In most instances, dia-

grams have been used whereon the situation of the distress has been accurately charted. It should here be stated that percentages indicated in the various groups are not mutually exclusive.

ESOPHAGEAL ULCER

The ulcers included in this group were situated just above the cardia. Pain usually was present or intensified during deglutition. Forty-five per cent of the patients noted a shift of pain upward to areas indicated in figure 1. Forty-five per cent gave a history suggesting peptic ulcer.

Fig 3—Left, nonperforating duodenal ulcers including subacute and larger ulcers. Right, perforating or deeply penetrating duodenal ulcers.

GASTRIC ULCER

More than 90 per cent of patients with shallow gastric ulcers complained of poorly localizable pain. Definite localization of pain was possible in 50 per cent of cases in which the ulcer was large or subacutely inflamed. In 90 per cent of cases in which the ulcer was perforating, the pain was accurately localizable to the left upper abdominal quadrant, usually near the costal margin. With invasion of the mesentery, mesocolon or abdominal wall, 93 per cent of patients noted secondary shifts of pain into the thorax or back (fig 2).

DUODENAL ULCER

Obstructing duodenal ulcer usually produced diffuse epigastric distress, frequently with a loss of the sequence of symptoms assumed to be diagnostic of ulcer. In 64 per cent of cases of nonperforating ulcer, the situation of the distress was poorly defined. Extensive or subacute ulcers frequently produced accurately localizable pain. In 90 per cent of cases, perforating duodenal ulcers produced pain which was localized with accuracy to the right upper abdominal quadrant. Seventy-seven per cent of patients with perforating lesions experienced a shift of the pain to the region of the liver or into the back (fig 3).

GASTROJEJUNAL ULCER

Pain caused by shallow ulcers in or about a gastro-enteric stoma is usually poorly localizable. Patients with perforating ulcers that involved a gastro-enteric stoma had definitely localizable pain, and furthermore they noted shifts of the pain into the lower portion of the abdomen or into the back in 88 per cent of cases. In 96 per cent of cases, patients who harbored perforating ulcers that were definitely jejunal in situation noted a downward or posterior projection of that pain. The situation of pain caused by perforating stomal ulcers that invade the anterior abdominal wall is usually on a higher level than in those cases in which such ulcers perforate posteriorly (fig 4).

ULCER OCCURRING ABOUT A MECKEL'S DIVERTICULUM AND GASTRO-ILIAC ULCER

The symptoms caused by an ulcer occurring about the orifice of a Meckel's diverticulum presented none of the characteristics usually attributed to peptic ulcer. When such ulcers were perforating, the pain was fairly well localized in an area to the right or left of and slightly below the umbilicus. The two gastro-iliac ulcers occurred in cases in which anastomosis had not been correctly made between the stomach and the ileum before the patients had come to the clinic. In both cases the symptoms maintained some of the characteristics usually noted in anastomotic ulcer. In one case the pain was indicated as being to the right of the umbilicus and, in the other, slightly above it. The pain in the latter was referred downward and through to the back, the lesion being a perforating gastro-iliac ulcer.

COMMENT

It should be stated that no definite rules of behavior can be formulated which invariably apply to the pain or the syndrome caused by peptic ulcer. The syndrome caused by such lesions usually maintains its original characteristics so long as there is no decided change in the morbid anatomic characteristics of such a lesion. Let the ulcerating process deeply invade the wall of the viscus, however, so that the serosa and, subsequently, tissues surrounding the gastro-intestinal wall are invaded and the characteristic picture of peptic ulcer usually becomes somewhat distorted.

The pain of a small, shallow peptic lesion is usually localized with some difficulty unless it produces mechanical disturbances, and this is true regardless of the position of such a lesion. It may produce no pain at all.

When the deeper tissues of the viscus are invaded, the syndrome as a rule becomes more definite and, with the origin of more severe pain, an area of more definite distress can usually be indicated with fair precision.

Fig 4—Left, nonperforating gastrojejunal ulcers including large and subacute ulcers. Right, perforating ulcers within or below the anastomosis.

When the inflammatory reaction is extensive, and especially when the lesion has penetrated to the tissues surrounding the viscus, a new area of pain may develop. The second pain may be noted in addition to the original pain, or it may supplant it entirely. Whereas in esophageal ulcer the original pain is in the vicinity of the manubrium of the sternum, it may later extend through to the back or upward into the upper portion of the sternum or into the neck.

In gastric ulcer the pain, in its inception and when the ulcer is shallow, is usually to the left and slightly below the umbilicus. With deep penetration, however,

there usually develops a shift of this pain to a definite area to the left of the median line, frequently approximately at the costal margin, and often there is further projection of this pain into the left portion of the back or upward anteriorly and laterally over the lower ribs. With duodenal ulcer the original pain is usually poorly recognizable although it is indicated as being above or frequently slightly to the right of the umbilicus.

With the development of subacute inflammation, and particularly when deep penetration occurs, the pain frequently shifts toward the right costal margin, and in addition there often develops projection into the right part of the back or upward into the region of the liver or right side of the thorax. Shallow gastrojejunal ulcers often manifest their presence by pain to the left of the median line or slightly below the umbilicus. When deeply penetrating or perforating, these ulcers frequently produce a shift of pain to the lower part of the abdomen, most frequently to the left side, although occasionally through to the back to a lower area than was the site of pain with the original duodenal or gastric ulcer.

With the onset of this secondary pain, other changes in the characteristics of the syndrome experienced by these patients frequently develop. There is less tendency toward intermittence of symptoms, less relief from distress by the use of food or alkalis, earlier onset of pain following meals and more distress at night. Frequently, abdominal tenderness becomes noticeable, and a rather persistent sensation of soreness may develop which usually is maximal over the area of pain. Frequently this pain is not in the ulcer sequence, nor is it relieved by food or alkali. This is particularly noticeable when extensive inflammatory reactions pass beyond the confines of the bowel and invade tissues surrounding the viscus. Although extensive or subacute lesions may be productive of the foregoing symptoms, definite penetration progression of the ulcerating process can usually be correctly assumed when the history reveals the presence of such changes from the original symptoms. The projection of pain into secondary areas does not necessarily occur with the development of acute distress. It frequently occurs and may be associated with much tenderness when the pain is and has always been mild.

With the development of obstruction there is frequently much distortion of the usual ulcer syndrome, the pain-food-ease sequence is often lacking, the retention type of vomiting may develop, and, in the presence of such a complication, the distress is usually indicated as diffusely spread out over the epigastrium. This is so regardless of the position of the lesion causing the obstruction.

The presence of several coexisting peptic lesions, if involving different segmental areas, such as an active duodenal ulcer and a gastrojejunal ulcer, may frequently be diagnosed by a careful consideration of the areas to which patients localize their pain. Very important lesions are not infrequently missed because dual pain areas and pain shifts are not carefully evaluated.

A definitely reappearing pain in a well localized area, with consistent projection of the pain to definite areas, may be more accurate than a roentgenogram in pointing out the gastro-intestinal segment from which such pain arises.

A minute scrutiny of pain is important in the recognition of the disease and of its complications, and in such

a crucible of clinical experience the theories regarding mechanics and pathways of such pain can be tested and applied. I have been impressed by the consistently recurring pain and pain projection experienced by various patients with lesions of identical histopathologic characteristics. The uniformity of these subsequently developing changes in situation and projection, depending on the depth of tissues invaded, is too definite to be a mere coincidence. Data are thus available to test theories and to ascertain whether they harmonize only with a single fact relative to the problem of pain in peptic ulcer or whether they are sufficiently flexible to be applicable to the problem of the varying behavior of this pain under different pathologic conditions. Among other considerations regarding the ulcer problem it should be clear why the pain of an ulcer that involves only the wall of the viscus, without extension to neighboring organs, should give an indistinctly localizable pain which only exceptionally shifts to other areas. It should explain, on the other hand, why the pain of an ulcer that invades neighboring tissues in the course of perforation should produce definite shifts with projection to secondary areas. It should lend itself to the explanation of why ulcers originating in identical tissues produce a definite posterior and lateral shift of pain when they penetrate to the mesentery and yet produce less definitely projecting pain that is on a different level when they perforate to the anterior abdominal wall.

It must also explain why the approved syndrome of ulcer may be present in the absence of ulcer, and why on the other hand extensive, subacute perforating peptic lesions frequently retain only the fragments of the syndrome that is assumed to be so characteristic of peptic ulceration.

A solution of these problems is not readily discernible in the hypothesis of Mackenzie.³ The splanchnic accumulation of pain impulses, and the relay of these peripherally as pain over the spinal sensory nerves, could be applied to explain some of the pain experienced by patients with ulcer. Mackenzie, when he formulated his hypothesis, did not believe that the splanchnic nerves carried sensory fibers. At the present time it seems an established fact that some sensory branches run along these splanchnic nerves.

The varying shifts of pain that occur when ulcers venture beyond the confines of the bowel can probably be explained more satisfactorily by the assumption of other routes than the splanchnic nerves. The hypothesis of Morley⁵ better fits the interpretation of the pain behavior of perforating ulcers. He suggested that such pain is picked up by the sensory spinal nerves and transmitted to the superficial branches of such nerves. He would classify the shifting distress of a perforating ulcer as a "referred pain." Regarding the origin of such pains he stated that "referred pain only arises from irritation of nerves which are sensitive to those stimuli that produce pain when applied to the surface of the body." He assumed that tissues such as the mesentery, mesocolon and abdominal wall are innervated by the sensory spinal nerves, a presumption which clinical experience would lead me to assume is entirely reasonable. I have noted, however, although I must admit that this occurred rarely, that projecting pains exactly similar to those observed in ulcers that invade tissues external to the bowel occasionally arise in ulcers that invade serosal tissues, and even rarely in ulcers which, although extensive, are not penetrating. This

could, of course, be explained on the basis of direct invasion of such tissues by products of inflammation or by unusually distended viscera, but I am not convinced that pain transmitted over the splanchnic route cannot be projected into secondary areas.

The slightly upward, left, lateral and posterior shift of the pain of gastric ulcer, the right, lateral and posterior shift of the pain of duodenal ulcer, and the downward, slightly lateral and posterior shift of the pain of jejunal ulcers all conform fairly well to peripheral areas supplied by somatic branches that could be expected to be invaded by posterior perforation of such lesions. In this connection the behavior of pain caused by lesions perforating to the anterior abdominal wall is interesting. In such instances there is local tenderness and rigidity, frequently a palpable mass, and the pain has less tendency to project widely. It is designated almost invariably as occurring in areas contiguous to the spot into which the penetrating lesion had attached itself. Furthermore, it is usually on a definitely higher level than is noted by patients having ulcers in identical positions but which perforate posteriorly.

It would seem that the most reasonable explanation for the various and varying situations and references of pain caused by peptic ulcer would have to assume at least a dual nervous mechanism. The simple, clean-cut, uncomplicated peptic ulcer may well be a visceral syndrome caused by rhythmically reasserting "adequate" stimuli and appreciated by means of afferent conducting mechanisms within the sympathetic nervous system.

The diffuse epigastric distress that is almost universally noted with obstructing ulcers, regardless of the position of such ulcers in the stomach, duodenum or jejunum, in all probability arises because of disturbed intragastric mechanics or disturbances in the stomach wall which could be a visceral phenomenon that would seem to be transmitted mainly along the sympathetic nerves.

With invasion, in the progress of perforation of tissues surrounding the wall inhabited by a peptic ulcer, it would seem that the warnings of the traumatizing effects of such invasion would be conducted over nerves guarding these tissues, which would probably be branches of the somatic nerves. These nerves being sensitive to many stimuli, in addition to the adequate stimulus producing pain over the splanchnic route, could be expected to produce a syndrome less rhythmic and clean cut than the syndrome caused by an uncomplicated ulcer.

The fact must not be lost sight of that, even though a perforating ulcer gets beyond the confines of its place of origin, it is still setting up irritation to the wall of the viscus. Thus impulses would be collected from both sources, that is, over the splanchnic and over the somatic nerves.

It is readily conceivable that the syndrome of peptic ulcer might well be influenced in this way. A disturbed ulcer syndrome, that is, one in which the symptoms are mainly over areas supplied by somatic nerves, could easily be assumed to receive predominance of impulses from without the bowel wall over branches from this system of nerves, whereas a pick-up of sensations over the splanchnic nerve plexuses not distracted by a mixture of impulses arising over the somatic nerves might conceivably be assumed to produce a syndrome usually accepted as being a characteristic peptic ulcer complex of symptoms. Much additional evidence will have to

be used by physiologists, anatomists, surgeons and clinicians before the final analysis of these varying phenomena associated with peptic ulcer and its syndrome will have been satisfactorily explained.

CONCLUSIONS

1 The clean-cut syndrome usually accepted as being diagnostic of peptic ulcer indicates an uncomplicated ulcer.

2 When the pain of gastric ulcer shifts definitely to the left, slightly upward or to the back, when the pain of a duodenal ulcer is projected toward the right, upward over the region of the liver or through to the back, or when the pain of a gastrojejunal ulcer extends downward or through to the back, one can usually correctly assume deep penetration or partial perforation of such a lesion.

3 The presence of two distinctly separated areas of pain especially if such pain is projected into two widely separated areas, frequently is indicative of two peptic lesions, such as an associated duodenal ulcer and gastrojejunal ulcer or an associated gastric ulcer high on the lesser curvature and a perforating duodenal ulcer.

4 The situation of the pain of an obstructing ulcer, regardless of the situation of the lesion, is usually diffusely spread out over the epigastrium.

5 Uncomplicated peptic ulcer probably indicates its presence as a visceral phenomenon, which asserts itself over the splanchnic nerves.

6 The projecting pain of perforating peptic ulcers are in all probability the result of direct stimulation of the somatic nerves with a relay of these impulses as pain into the peripheral or cutaneous branches of such nerves. It is conceivable that the distortion of the approved ulcer syndrome in such instances is influenced by the accumulation of impulses of varying intensity over both the splanchnic plexuses of nerves and over the somatic nerves.

ABSTRACT OF DISCUSSION

DR RALPH C BROWN, Chicago. Dr Rivers has clearly outlined the extent to which confusion still exists among physiologists with respect to the precise mechanism of peptic ulcer pain. However, a mass of accurate clinical data is now available, established facts that are of the greatest value in differential diagnosis. It is known that an ulcer not complicated by an extensive perigastritis gives rise to pain or distress only when free hydrochloric acid in considerable concentration is in contact with the exposed surface of the ulcer. Free hydrochloric acid is without doubt the direct irritant that initiates the pain. As a striking illustration I would cite two cases of gastrojejunal ulcer recently under my observation. With clocklike regularity about one and one-half hours after food-taking, pain would appear in the left testicle, would increase to almost agonizing intensity, and would continue until relieved by giving the patient food or an alkali. Relief of the testicular pain in these patients by hydrochloric acid neutralization was immediate and complete. In these two cases the left renal nerve supply had become involved in the inflammatory mass surrounding deeply penetrating jejunal ulcers. The nerve supply to the kidney and to the testicle is derived mainly from the sympathetic through the solar and aortic plexuses and from the splanchnics. It would be difficult to explain the testicular pain in these cases of jejunal ulcer on any basis other than direct chemical irritation of the renal nerves thus exposed in the base of these ulcers. The relief from alkalis was immediate and complete. It seems to me highly improbable that the pain of ulcer can be explained on the basis of increased intragastric tension. In certain cases of high grade pyloric obstruction of long standing, with great hypertrophy of the stomach musculature, the visible and palpable gastric peristalsis forms globular masses having almost the

firmness of a grapefruit. The intragastric tension at such a time must be very great, yet no discomfort is experienced by the patient. I do not believe it is possible to determine accurately the location of an ulcer by the localization of the pain or distress. The characteristic response of the patient with an active ulcer, whether gastric or duodenal, when asked to indicate the site of distress, is the unhesitating placing of one or two finger tips at one definite point in the epigastrium. True this point will vary in different individuals, but most commonly it is in the midline. Less than 10 per cent of patients with active ulcer will indicate the site of distress with the palm of the hand. This point is of definite diagnostic value, especially in differentiating the pain of ulcer from that caused by a spastic bowel.

DR. FRANK SMITHIES, Chicago. It is necessary to diagnose not only peptic ulcer but its localization as well. If it is in the stomach, the prognosis is different from that of an ulcer in the duodenum. There is the greater possibility of serious complications when the ulcer is gastric. Likewise the histologic state of the ulcer must be diagnosed. This is most essential with regard to the exhibition of proper treatment. By the time the gastro-enterologist sees the patient, his clinical story is that of what happens in consequence of various types of complications—these all affect what happens secretorily, from the standpoint of motility and interference with general nutrition. Hence the symptomatology of progressive ulcer is an ever changing one, so are the special laboratory observations. Dr. Brown has emphasized how mild may be the symptoms of chronic ulcer, and he has done that, I am sure, with the object of emphasizing the fact that chronic ulcer is not especially a mucosal disease. It is a mural disease—a periduodenal and a perigastric disease. I want to point out an observation which I think is important. Sometimes one sees a patient with pain diffused over an area requiring a hand to cover it. If that patient begins to have marked distress in one place, and it begins to have a definite point of reference to the back, up to the teeth (I have seen teeth taken out because such pain supposedly was due to bad teeth), to the shoulder to the nipple, or is angina-like and if the pain reference point always is to one place, the clinical interpretation is that a histologic complication is occurring in the ulcer whether the lesion is gastric or duodenal. When, in addition to the constancy of the patient's description of distress, one elicits local tenderness, one is being told by a pathologic process that there is a histologic change going on and that one is dealing with something entirely different in the ulcer. In such circumstances one may expect serious consequences to occur even though at intervals the patient is in the greatest of comfort. The lesion has passed from its mucosal to a definitely mural stage with possibilities of serious vascular or motor accidents. The author did not emphasize the point of reference of pain by the patient to the region in which tenderness is noted, but what I have suggested is a hint. Relief of pain in ulcer doesn't concern physicians today. There are many mechanisms—the Christian scientist, a highball, a lot of alkali, a baseball game and so on. The mechanism of relief varies with the individual, and possibilities for relief frequently depend on the histologic status of the ulcer at the particular time.

DR. SIDNEY K. SIMON, New Orleans. One of the inferential points brought out in Dr. Rivers' splendid contribution is the stress that he lays on a purely clinical phenomenon in the diagnosis of ulcer. The great tendency in recent times in the diagnosis of gastro-intestinal conditions has been to stress largely the laboratory phenomena, very often at the expense of clinical interpretations. Dr. Rivers shows clearly the importance of just one simple phase of the clinical data, and that is the proper interpretation of the pain location. I should like to ask the author what his impression is in regard to the localization of points of tenderness, in relation to the somatic description of the pain by the patient. The older clinicians learned to depend to a certain extent on the location of areas of sensitiveness for the differentiation of the gastric from the duodenal ulcer. The description of the painful area along the spinal column or to the left, rather, of the spinal column, by Bowers has been stressed and I should like to know from Dr. Rivers whether he has correlated in any way in his own observations these various areas of sensitiveness or head zones or Boas's

points in relation to the differential diagnosis of the different phases of peptic ulcer.

DR. A. H. AARON, Buffalo. The responsibility of the correct interpretation of pain rests with gastro-enterologists. I will mention two cases. A woman had a sudden terrific pain in the upper part of the left diaphragm, referred to the neck, and was in shock. The diagnosis was made of a perforated lesion of the stomach and gastrostomy was done. She died. An ulcer was found at the junction of the cardia in the stomach, which had perforated and also crowded a large vessel. She had the typical referred pain to which Dr. Capps called attention, which she could reproduce by mechanical stimulation of the inner portion of the diaphragm which received its innervation through the phrenic, and referred pain to the neck. In the second case the situation was more serious. A man had terrific pain referred to the neck. It was diagnosed as coronary thrombosis, but what he actually had was an ulcer in the esophagus. The patient unfortunately presented cardiographic changes, was in collapse, had referred pain such as Dr. Rivers described, and was on a restricted regimen for a long time. He altered his whole conduct in life, the character of his activities, and what he really had was revealed on examination of the esophagus to be a peptic ulcer of the esophagus. The referred pain was due to that. He had somewhat of an effort syndrome associated with his pain.

DR. ANDREW B. RIVERS, Rochester, Minn. Dr. Brown intimated that it is not always possible to localize ulcers correctly from the situation of their pain. This is particularly true with ulcers that do not have penetrating characteristics. If ulcers are of the penetrating variety, it is frequently possible to localize with a fair degree of accuracy the position of the lesion. However, this does not preclude the necessity for corroborating such impressions by roentgenologic investigations. If an ulcer has been localized under the fluoroscope and these pain shifts occur, the probability of a complicated histopathologic condition of the ulcer is suggested. There are still many things regarding the mechanism of pain production in ulcer that are unsettled. There seems no doubt that acid is one of the chemical causes for the production of pain. However, whether acid is responsible for the production of pain by bringing into play some other related mechanism, such as spasm, is not finally determined as yet. Regarding the matter of tenderness in peptic ulcer, I doubt that the situation of such tenderness always corresponds to the position occupied by the ulcer. There are some suggestions that in extensive peptic ulcers there may be visceral tenderness. On the other hand, it seems likely that in most instances the tenderness associated with penetrating lesions is due to actual somatic invasion. This may be due to direct peritoneal irritation, or it may at times be felt along the distribution of the somatic nerve affected by such nerve irritation.

The Physician of the Gods—The Romans followed the Greeks in regarding Phoebus Apollo, the physician of the gods as the inventor of medicine. By the nymph Coronis, who seems to have indiscreetly joined the god while he was bathing in a river, Apollo had a son Aesculapius. He entrusted the education of the boy to the centaur Chiron, who taught him the charge the art of medicine. Arrived at manhood, Aesculapius performed many miracles of healing but his very efficiency proved his undoing. It happened in this way. The seer Polydus while watching by the body of the dead Glaucus, saw a snake approaching and promptly killed it. In a few moments, however, he observed a second snake which drew near its dead companion and touched the lifeless body with an herb that it carried in its mouth. At the touch, the dead snake instantly revived. Polydus communicated his discovery to Aesculapius, who used the same herb to restore the life of Hippolytus, whose death had been brought about by his incestuous stepmother, Phaedra, the Greek counterpart of Potiphar's wife. Jupiter incensed that a mortal should usurp the divine prerogative of raising the dead, blasted Aesculapius with a thunderbolt. After his deification a temple was erected for the worship of Aesculapius at his birthplace, Epidaurus, a town in the Peloponnesus about thirty miles from Athens—Jeffrey, Eric. *The Ancient Romans Through Medical Eyes* *Am J Australia* 2: 439 (Oct 6) 1934.

ULCERATIVE COLITIS

II THE FACTOR OF DEFICIENCY STATES

THOMAS T. MACKIE, M.D.

WITH THE ASSISTANCE OF MISS MADFLEINE HENRIQUES
NEW YORK

During recent years the concept of deficiency disease has been enlarged. It is becoming increasingly apparent that chronic vitamin deficiency produces a variety of vague borderline states of ill health that have no place in existing nomenclature. These conditions, however, seldom appear uncomplicated or well defined. The contributory factors are more complex than those operative in the laboratory, where the environment of the experimental animal is subject to strict control. It is probable, therefore, that the resulting clinical picture in man is not the simple expression of lack of a single factor as a vitamin. Deficient supply of other essential food substances such as protein, iron, calcium, phosphorus and iodine undoubtedly contribute to the syndrome.

We have encountered indications of deficiency disease in forty-seven cases of chronic ulcerative colitis. These observations have been drawn from seventy-five consecutive cases seen in hospital, dispensary and private practice in New York City. They represent all stages of the disease anatomically from mild localized proctitis to advanced and extensive involvement of the entire colon. The clinical expression has varied from the mild form with relatively slight symptoms to the very severe type requiring prolonged periods of hospitalization and, at times, surgical intervention.

In most instances the phenomena suggesting deficiency disease have not been associated with a clinical picture that coincides exactly with any of the well recognized conditions usually included within this group. The diagnostic criteria that we have adopted have been restricted to the objective changes that have been shown to occur in various deficiency states. They find expression particularly in the mucous membranes of the mouth, in the skin, in changes in the blood chemistry, and in the associated anemia.

Alterations in the mucous membrane of the tongue have been the most common of the abnormal manifestations. They appear to be among the earliest recognizable indications of deficiency disease. They present the features that are characteristic of sprue, pernicious anemia and pellagra. The initial phase begins as an inflammation of the fungiform papillae over the anterior third. This causes them to stand out with undue prominence and leads to a strawberry-like appearance. If progression occurs, a diffuse glossitis develops in which the anterior portion of the tongue becomes inflamed, red and often tender. At this stage small, painful aphthous ulcers may appear and may be present also on the buccal mucosa. Ultimately, as is the case in sprue, the filiform papillae degenerate and the characteristic smooth atrophy of the tongue results. More rarely, and only in the advanced and serious cases, the inflammatory process has extended to involve the mucous membrane of the mouth, producing a condition indistinguishable from the diffuse stomatitis of pellagra.

These changes are relatively slight in many instances and may easily escape notice. The smooth atrophy is frequently restricted to the tip and to the edges of the tongue. It is seldom as prominent as in Addisonian anemia.

Eleven of the patients have presented abnormal conditions of the skin. These individuals, with one exception, were seriously ill. The cutaneous phenomena that appeared in the course of prolonged hospitalization did not exhibit the characteristics of infection or of response to common irritants. They were preceded or accompanied by other clinical indications of deficiency.

Alteration in the texture of the skin has been the most common change observed. It becomes abnormally dry and scaly, especially over the extremities. This is frequently associated with hyperkeratosis follicularis and a harsh, almost sandpaper-like skin surface. With general clinical improvement these phenomena have receded and have given place to normal soft and elastic integument.

Symmetrically disposed atrophy of exposed skin surfaces has been noted in five of the patients. This has usually, but not invariably, followed exposure to sunlight. The changes, however, have been noticeably disproportionate to the degree of sunburn. This has been most evident over the dorsum of the hands. In one case, however, the scapular region was similarly affected and in another the greater portion of the extremities.

was involved. The skin in these instances is dry, wrinkled, parchment-like and transparent.

We have noted a variable type and degree of dermatitis in three of the cases. One patient developed a classic pellagra after exposure to the sun, with acute inflammation of the exposed areas and an acute diffuse stomatitis. These phenomena cleared rapidly on the parenteral administration of liver extract. Pigmentation followed the cessation of the inflammatory process in the skin. The other cases probably represent incipient pellagra. In one a symmetrical smarting dermatitis appeared over the metacarpophalangeal joints of both hands and over both heels. In the other, a similar process developed over the extensor surfaces of the elbows and over the anterior surface of both knees. In two instances a brownish discoloration of the face and flanks appeared without antecedent dermatitis, analogous to the pigmentation in sprue.

A discrete maculopapular erythematous eruption developed in two patients during their stay in the hospital. In neither instance did these changes follow on exposure to any known etiologic agent, and the consulting dermatologist was unable to classify them with certainty. The individual lesions varied from a few millimeters to a centimeter or more in diameter. They were reddish brown or copper colored, discrete, slightly raised and indurated but not tender, painful or itching. They were largely restricted to the extensor surface of the hands, forearms and arms, and the calves of the legs. There was no involvement of the palmar surface of the hands, the lesions appearing only on the

dorsum Liver extract seemed responsible for their disappearance in the one case in which it was used

An extensive and spreading skin gangrene of the flank occurred suddenly following ileostomy in another patient, who presented changes in the buccal and lingual mucosa strongly suggestive of pellagra The initial focus of the gangrenous process was not immediately adjacent to the operative field and multiple secondary foci appeared, which were completely surrounded by normal skin These changes could not be attributed to trauma, mechanical or chemical, and aerobic and anaerobic cultures failed to throw light on the etiology

Diffuse stomatitis	4

Both the protein and the mineral metabolism of the body may be seriously disturbed in the advanced stages of chronic ulcerative colitis Blood chemistry determinations have shown marked deviations from normal in seven cases These patients were seriously ill and without exception presented other indications of deficiency disease The total plasma protein was below normal limits in four In three of these this change was associated with inversion of the albumin-globulin ratio and extensive edema The serum calcium values were lowered in four cases However, this reduction was not sufficient to induce clinical evidence of tetany The total base was below normal in one patient who presented a severe grade of malnutrition

Thirty-nine of the seventy-five cases have shown significant grades of anemia In thirty-one the characteristics of the hypochromic microcytic type were constantly present The color index remained uniformly below unity, the average cell diameters as measured by the Eve halometer, were low, and microcytes predominated in the stained smear

Eight of the cases, on the other hand, have presented an anemia that is difficult to classify All but one of these patients exhibited other evidence of deficiency states The color index has varied irregularly to both sides of unity when followed over a period of months With indexes at unity or above, the average cell diameter has tended to exceed 7.5 microns and the stained smear has shown varying numbers of macrocytes These variations persisted until liver extract was added to the therapy With this, the index has remained constantly at lower levels and the stained smear has presented the characteristics of the simple or iron deficiency anemias The gastric acidity studies are inconstant in this group In two patients a normal response to histamine was obtained Hypo-acidity was present in one, and complete anacidity in four Four of these patients showed varying degrees of smooth atrophy of the tongue There was no evidence of subacute combined sclerosis

These phenomena in the buccal mucous membranes, the skin and the blood have been observed in various deficiency diseases in man Although the association does not prove conclusively that these changes result from the deficiency, accumulating clinical experience supports the belief that they may be accepted as dependable indications Determination of the specific factor or factors responsible for the development of a

particular lesion is quite another matter, however The results of experimental studies have frequently been contradictory Much of the early work in nutrition must be reevaluated in the light of subsequent knowledge Diets that were believed to be deficient in one principle have later been shown to be lacking in several Consequently the original deductions are inaccurate.

Inadequate supply of the vitamin B complex seems to play a part in the production of lesions in the mouth Hutter, Middleton and Steenbock¹ have regularly produced smooth atrophy of the tongue in rats maintained on diets that were believed to be complete except for vitamin B₂, or G On the other hand, Zimmerman and Burack² have studied the effect of what they consider to be an uncomplicated B₂ deficiency in dogs Weight loss, vomiting, diarrhea and muscular weakness developed in the animals, finally ending in death They found lesions of the nervous system, an intact gastro intestinal mucous membrane, and no evidence of dermatitis, gingivitis or glossitis The cutaneous and oral lesions of pellagra are believed to be closely related to deficiency of this substance and have been shown to respond to the continued administration of various preparations of liver³ Regeneration of atrophic lingual papillae in man has been observed when a good source of the B complex such as yeast is added to the dietary Similarly, the oral or parenteral administration of liver extract has been followed by restoration of the tongue to normal⁴ In our cases the feeding neither of yeast nor of liver extract has seemed completely effective. When given intramuscularly or intravenously, however, the latter has checked the aphthous ulceration and the diffuse stomatitis Progressive regeneration of the atrophic lingual papillae has resulted when it was administered over a sufficient period of time

It is probable that skin lesions other than the dermatitis of pellagra are related to a deficient supply of these vitamins Cowgill, Stucky and Rose⁵ reported that in dogs kept for long periods on diets adequate except for the entire vitamin B complex, cutaneous lesions developed, which frequently were symmetrically dis-

The significance of the discrete symmetrically disposed skin eruption and of the one case of skin gangrene that we have observed is difficult to determine accurately. However, the association with other more dependable indications of deficiency disease suggests that they result from the same mechanism.

Deficiency of vitamin A has been shown to produce epithelial hyperplasia, metaplasia and keratinization.⁷ Hyperkeratosis about the hair follicles particularly on the extensor surfaces of the arms and legs and over the abdomen has been attributed to lack of this factor. The sweat and sebaceous glands atrophy. The epithelium of the hair follicles undergoes keratinization, causing it to project as a plug above the surrounding skin surface.⁸ The skin becomes dry, scaly and shriveled.⁹ These changes, together with acneform eruptions, have recently been observed associated with night blindness and xerophthalmia. Both the cutaneous and the ocular phenomena disappeared on the addition of cod liver oil to the dietary.¹⁰ Although none of our cases have exhibited xerophthalmia or night blindness recent work indicates that these conditions probably result from advanced grades of deficiency and that minor degrees of vitamin A deprivation are not uncommon in the general population.¹¹

The abnormal blood chemistry studies and the disturbed fluid balance may represent an inadequate available supply of protein and of electrolytes or an excessive loss of these substances from the body. The edema that we have observed in these cases exhibits the characteristics of the so-called nutritional, or war edema. This results from the change in osmotic relationships attendant on reduction of the blood proteins. Moschowitz¹² has encountered this condition in three cases of ulcerative colitis with chronic diarrhea. He considered the protein deficit to be the result of exudation of serum from the ulcerated surface of the colon. While this constant loss unquestionably plays a part, we believe that the deficient available supply is also a factor of some importance.

The cases with varying color index anemias and inconstant macrocytosis suggest an irregular and slight deficiency of the hematinic principle requisite for normal erythropoiesis. Since the diets of these patients were rich in extrinsic factor, the defect must lie in insufficient production of intrinsic gastric factor or in imperfect absorption from the intestine. The net effect, however, appears to be intermittent in action and insufficient to produce the complete picture of true macrocytic anemia, although the blood picture borders on this condition.

These varied indications of deficiency disease have appeared in spite of dietaries that are completely adequate for the normal individual. Stool examinations have not revealed sufficient evidence of faulty digestion to account for their occurrence. Consequently our attention was attracted to the function of the small intestine. It seemed possible that one or both of two factors might be responsible for the development of

deficiency states in the presence of a complete diet. Hypermotility might cause too rapid a rate of passage through the tract, or a defect in the absorbing mechanism might offset an apparently adequate diet.

Twenty-nine of thirty-seven cases studied roentgenographically have shown significant changes in the small intestine. These frequently extend from the duodenum to the ileocecal junction. The normal mucosal pattern is distorted, as though the mucosa, and especially the valvulae conniventes, were edematous. There is dilatation of individual coils and groups of coils without evidence of obstruction. There is disorganization of normal motor function with reduction of activity and uncoordinated muscular contraction. No evidence of ulceration of the small intestine has been obtained. These changes have been constantly present and most marked in patients with advanced grades of deficiency disease.¹³

Exact interpretation of these studies of the small intestine is impracticable at present. There are clinical and experimental observations, however, which suggest that they may themselves be the expression of deprivation of the vitamin B₁. Anorexia has been a troublesome clinical problem in many of our cases. This symptom has been shown to be one of the most characteristic effects of partial deprivation of the antineuritic

vitamin, and it appears well in advance of polyneuritis.¹⁴ We have encountered the latter condition in only one case. Furthermore, reduced motor activity of the intestinal tract has been observed in animals on the withdrawal of this vitamin from the diet.¹⁵

Deficiency states have been observed in ulcerative colitis in the past. Jones¹⁶ considers them not infrequent, and Dickson¹⁷ and Larimore¹⁸ have suggested that avitaminosis might play an important rôle. However, the clinical pictures of the recognized deficiency diseases are relatively infrequent. The lack of correlation between the objective phenomena developing in animals on experimental diets and those observed in man have interposed obstacles to the development of this concept. Although the experimental evidence is striking, clinical experience has not supported the view that avitaminosis may operate as a primary cause of the disease.

Our studies, on the other hand, lead us to believe that deficiency states play an important part in the

mechanism of chronic ulcerative colitis. We have observed indications of such conditions in 62.6 per cent of our cases. The lack of clinical signs of deprivation in the remaining cases suggests that the factor of deficiency is secondary rather than primary. The serious chronic cases have invariably presented moderate to marked grades of deficiency disease. The general clinical improvement attendant on control of this factor indicates the importance of specific therapy. The development of these conditions despite a balanced diet suggests that they result from some fundamental disturbance of physiology secondary to the diseased colon. The changes demonstrable in the small intestine may impair the absorption of the normal end products of digestion and so give rise to the paradox of deficiency in the face of adequate intake. In support of this possibility we have observed identical changes on roentgen examination of the small intestine in three cases of sprue, a disease that is characterized by blockage of the absorptive mechanism.¹⁰

We believe, therefore, that deficiency disease is not to be regarded as an occasional complication of chronic ulcerative colitis. It seems more probable that it constitutes an essential part of the underlying mechanism. With the appearance of indications of deficiency disease the pathology changes, the symptoms become more complex, the clinical picture more severe, and the prognosis more grave. In many instances the evidence does not permit definite evaluation of the role of single vitamins or specific food substances. The clinical phenomena suggest, however, that the deficiencies are multiple rather than single. Inadequate supply of vitamins A, B₁, B₂, and possibly D, together with lack of biologically complete protein, and of electrolytes, appears to contribute to the complex clinical picture in varying degree. The progression that many of the patients have shown under prolonged observation suggests that the potentially severe and untreated or imperfectly treated case tends to pass through three stages. In the initial phase clinical evidence of deficiency disease is lacking. The second stage is characterized by the appearance of early signs of deficiency. In the third stage, which is relatively rare, deficiency disease is severe and tends to dominate the clinical picture.

CONCLUSIONS

1 Evidence of deficiency states has been observed in 62.6 per cent of seventy-five cases of chronic ulcerative colitis.

2 These indications find expression in the buccal and lingual mucosa, the skin, the type of anemia and the blood chemistry.

3 When present in advanced degree they have invariably been associated with characteristic changes in the small intestine.

4 Secondary, or conditioned deficiencies appear to be important factors in the pathologic physiology of the disease.

THE CRITERIA OF CURE OF GONORRHEA IN THE MALE

AMBROSE J. KING, FRCS (ENG.)
LONDON, ENGLAND

There is no phase of the management of cases of gonorrhea that gives rise to more anxiety to the clinician than the period of probation preceding the decision as to cure. There are few errors that may be fraught with such disastrous consequences to the patient and his family, and to the reputation of the doctor, than an error in this important decision. Yet only too commonly it is found that, without adequate thought and without careful observation, this heavy responsibility is readily and lightly accepted.

In the time at my disposal I propose to enumerate the various points that must be considered in approaching such a decision, to give my views based on clinical observations in conjunction with certain improved pathologic tests, and to provoke discussion of those controversial points by which new light may be thrown on this old problem.

The tests of cure may with propriety be divided into two chronological groups, the classic and the modern. The classic group of tests are in the main clinical and imply a searching physical examination of the lower urogenital tract. Briefly, the requirements are an absolutely clear urine both by gross and by microscopic tests, negative endoscopic examination, absence of any evidence of inflammation in the urethra, testes, prostate and seminal vesicles, and a prostatovesicular fluid containing no organisms and not more than 5 white cells to the high power field. These requirements sound reasonable enough, yet it is my belief that a majority of patients affected with gonorrhea cease treatment before achieving these classic standards of cure. Of those who measure up to these requirements many have been found, on follow up, to develop recurrences or metastatic lesions or to infect a sexual partner. It has become more and more obvious, as apparently cured cases are followed over long periods, that the classic tests furnish a most insecure index of cure. In the past many attempts have been made in the direction of greater accuracy in diagnosis of residual or latent infection, thus, the complement fixation and cultural methods are quite old—actually the complement fixation test was introduced in 1906. It is only in recent years, however, that intensive work all over the world has led to the perfection of the complement fixation and cultural methods, thus providing a secure pathologic test of cure.

These modern tests demand a high degree of accuracy and experience on the part of the pathologist. They are of course complementary to the clinical tests and in no wise supplant them.

CULTURAL TESTS

Experience shows that cultural tests of the prostatic fluid alone are not reliable. Every effort should be made to obtain as much as possible of the contents of both prostate and seminal vesicles.

Much recent clinical and pathologic evidence points to the fact that infection of the seminal vesicles occurs in a considerably higher proportion of cases than is generally stated. A detailed discussion would be out of place here, but at least the careful microscopic and

Read before the Section on Urology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

cultural examination of both fluids requires no extra effort and will give more accurate results

The technic of culturing the gonococcus from the vesiculoprosthetic contents in the chronic stage of gonorrhea is due to work of Dr Orpwood Price, pathologist to the Whitechapel Clinic, and has been in routine use for the last two years. The procedure is as follows: The patient passes urine and the anterior urethra is then irrigated with sterile water. The patient assumes the knee-elbow position and the prostate and seminal vesicles are massaged thoroughly. As much as possible of the expressed fluid is allowed to drop on the surface of a culture medium contained in a petri dish. The cover of the dish is replaced and the surface is slanted in all directions so that the greatest possible area of surface is inoculated. Before inoculation the medium is kept for at least half an hour in the incubator at 37.5 C and is replaced immediately after inoculation. The culture is incubated for five days, it is premature to examine for gonococci before this period has elapsed. A variety of organisms may be present but the most constant feature is a profuse growth of *Staphylococcus albus*. Owing to the strong secondary growth, the gonococcus colonies may be difficult to distinguish without the use of a differential stain. For this purpose the oxidase reaction is employed.

The oxidase reaction was first used for differential diagnosis in bacteriologic work by Gordon and McLeod in 1928 and was adapted by Price to the isolation of the gonococcus in mixed culture in 1929. Briefly, the test depends on the interaction of the oxidizing ferments in certain organisms and a reagent—in this case 1 per cent dimethylparaphenylenediamine hydrochloride in distilled water, which produces a color reaction. The solution should be freshly prepared.

This solution is poured over the surface of the medium so that it comes into contact with all the surface growth. A positive reaction is shown by certain colonies developing a pink coloration, which deepens through shades of purple to jet black in about thirty minutes. These colonies can then be picked off and stained by Jensen's modification of Gram's method, when they will be seen to consist of gram-negative diplococci morphologically indistinguishable from gonococci. These are always closely associated with staphylococci, which in the first three days of incubation mask but do not inhibit their growth. Indeed, one of the most interesting features of cultures prepared and examined in this way is the appearance that is constantly seen of the gonococcus colonies growing up through the larger colonies of *Staphylococcus albus*.

The oxidase reaction is not, of course, a specific test, and other members of the neisserian group give a positive reaction. Of these only *Micrococcus catarrhalis* gives a closely similar reaction, but this organism is rarely found in the genital tract.

False positive reactions are usually given by a thin filament type of *B. coli*, as well as by *B. subtilis*, but these are easily distinguished by microscopic examination of the organisms when picked off the plates. If difficulty arises it is possible to make an antigen from subcultures and to titrate against a known antiserum.

Culture tests carried out according to this technic have proved most reliable and most informative. Its routine use throws light on many clinical points that have been obscure hitherto, and there is no doubt that it constitutes a very considerable advance in the methods of diagnosis of gonorrhea in the chronic stage. As a test of cure it is invaluable.

It must be emphasized that one negative test is never sufficient and, although this cultural examination has proved to be the most delicate and reliable of tests, it can be accepted as a criterion of cure only in conjunction with negative clinical observations and the other negative pathologic tests.

In our test of cure we apply this test monthly during the period of observation without treatment. A series of four negative tests would be the minimum that could be regarded as satisfactory. In a series of 100 patients without symptoms the test was positive in 100 per cent. What evidence have we for asserting that the gram-negative diplococcus which we recover in our cultures is the gonococcus?

Apart from the skill and experience of our pathologist, the evidence is threefold:

- 1 The oxidase reaction within the limits I have indicated is specific for this type of organism.

- 2 The titration of an antigen made from subcultures of the organism against a known gonococcus antiserum will give a positive result to the complement fixation test.

- 3 We make every endeavor to examine and test the husbands of married women who attend our clinic for vaginal discharges which are clinically and bacteriologically gonococcal.

It is a frequent experience that the husband of such a patient has no signs or symptoms of gonorrhea but gives a history of urethritis some years previously. In such cases we are able, almost invariably, to recover this organism in vesiculoprosthetic culture.

THE COMPLEMENT FIXATION TEST

The complement fixation test for gonorrhea is an invaluable aid in all stages of the management of gonorrheal cases.

In 1933 Price introduced a new antigen and improved the technic by using more concentrated serum. As the result of his work the sensitivity of the test is much improved and its value as a criterion of cure is enhanced.

False positives by "cross-fixation" for practical purposes do not occur and we find that a positive reaction in the serum of a patient who has not been treated with gonococcus vaccine is an absolute indication of a persistent focus of infection with the gonococcus.

In a series of cases treated with gonococcus vaccine it was my experience that when cure could be established the complement fixation test became negative within six weeks of the cessation of vaccine administration. A positive result after this interval invariably indicated residual infection.

On the other hand a negative serum result to the complement fixation test, even in the symptomless patient, can never be accepted as reliable evidence of cure or anything more than a sign of good progress and efficient drainage. In many cases we are able to demonstrate the gonococcus in the secretions long after the test has become and has remained negative.

Some variation in the strength of the fixation test is to be expected in the period that precedes cure, and no single negative reaction should be regarded as conclusive serologic evidence. It is our custom to perform the test at the beginning and at the end of our period of observation and testing. It is a common experience that, when treatment is prematurely discontinued and the patient remains under observation, the fixation test will again become positive, thus indicating a persistent focus of infection.

A provocative diet including alcohol is of assistance in the final stages. I have had no satisfactory results from provocative injections of vaccine or from provocative urethral instillations.

SUMMARY

1 No investigation as to cure need be undertaken in the gonorrheal patient who has a persistent urethral discharge or whose urine shows evidence of infection. To this main principle there may rarely be exceptions.

2 Palpation of the prostate is seldom of much assistance in the treated case. Palpation of the seminal vesicles is likely to give some positive information, but this is of little value when vesiculitis has been recognized and treated.

3 The macroscopic examination of the vesicular fluid and the microscopic examination of the vesicular and prostatic fluids are of great importance. Unsatisfactory microscopic tests are strong evidence against cure.

4 Vesiculoprosthetic culture by Price's method constitutes an important advance in accurate diagnosis. The test repeated at monthly intervals over a period of time constitutes the absolute criterion of cure when all other tests have proved satisfactory.

5 Recent improvements in the complement fixation test for gonorrhea have increased its sensitivity and enhanced its value in testing for cure.

6 A positive serum result in a patient who has not received injections of gonococcus vaccine within the preceding six weeks is reliable evidence against cure.

7 Negative blood serum results on successive occasions in the course of treatment are evidence of efficient treatment but not necessarily of cure.

8 A provocative diet, including alcohol, is sometimes of value as a preliminary to the final series of tests and should be employed.

CONCLUSION

Let me review the evidence against cure in a clinically well patient. A negative complement fixation test may merely mean efficient drainage, it can and does occur when even smears are positive. What is the meaning of repeated positive cultures? I feel that while striving for accurate and infallible criteria of cure, we have arrived at the unenviable position of having apparently proved that cure is very much more difficult of achievement than is generally realized.

Further, it appears that the clinically well patient, having established a biologic equilibrium with his gonococci, retains the power of transmitting virulent infection to his sexual partner. Despite the work, time and thought given by us to this subject, I do not feel that we have arrived at conclusions which warrant more definite formulation. I do feel, however, that we have been able to establish the fallacies of previously accepted standards of cure. This paper is presented as an account of the work of the Whitechapel Clinic up to the present, so as to set forth our observations and difficulties and in the hope of enlisting cooperation and help in the work that lies ahead in the attack on the bristling problems of this ancient social menace.

ABSTRACT OF DISCUSSION

DR. MILEY B. WESSON, San Francisco. There is an aphorism in common use to the effect that "gonorrhea is no worse than a bad cold," and now our guest of honor tells us that gonorrhea is practically never cured. Somewhere in between these two extremes lies the truth. Theoretically, a man who has never had a genito-urinary tract infection should not have palpable

seminal vesicles. Practically, it is almost impossible to find a microscopic section of the prostate of an adult that does not show evidence of inflammation. A number of years ago, Dr. Hugh H. Young wanted a set of normal sections of the genito-urinary tract. Eventually in order to get a normal prostate section to complete the set he used that of a newborn baby. Most of the men who have contracted gonorrhea marry sooner or later. If the disease were not primarily self-limiting in type, a large proportion of marriages would be of the sterile or one-child type. In some states men are required by law and in others by their innate sense of decency to consult physicians when they desire to marry. The prostate gland and seminal vesicles are common sites of focal infections and from that standpoint are comparable in all ways to the tonsils or the gallbladder. Pus in the seminal vesicle does not mean that the man has had gonorrhea, although for fear that he did have it and that the gonococcus has been replaced by secondary invaders, I insist that he have the infection cleared up to protect not only his wife from a leukorrhea but himself from low backache secondary to arthritis or myofascitis. The cultural tests that Mr. King describes are intriguing. However, the strains of gonococcus prevalent in the United States will not grow on ordinary mediums but require special mediums and a decreased oxygen tension. Furthermore, there is no evidence that these are not atypical staphylococcus. Before an organism can be positively identified as the gonococcus it must be intracellular. The oxidase reaction would be valuable if a method of incorporating the dye in the medium could be worked out as suggested by Gordon and McLeod. Of course, the fact that it is not specific for any organism since *Bacillus pyocyaneus*, *B. subtilis*, *Micrococcus catarrhalis*, *M. flavus* and the neisserian group react to it impairs its efficiency. Orpwood Price reports that his antigen will give a complement fixation test that is as accurate as the Wassermann reaction. If this is so, a big advancement in the study of this disease will be made, when the test comes in general use. Vaccine treatment has not proved satisfactory in most clinics, and I believe there is far less used now than there was a few years ago. The gonococcus filtrate (Corbus-Ferry) is expected to give better results. I should like to ask Mr. King what his experiences have been with *Diplococcus crassus*. I have seen it in three patients, and the varied sizes of the gram-negative diplococci in the pus cells made a striking as well as confusing picture.

DR. JOSEPH A. HYAMS, New York. I feel that in most instances the persistence of a urethral discharge is due to complicating factors rather than to the gonococcus per se. Digital examination of the prostate with cultural and microscopic study of the expressed prostatovesicular secretion gives valuable information as to the persistence of an infectious process, but digital palpation of the seminal vesicles may be subject to erroneous interpretation, owing to the varying amount of supporting areolar tissue, and anatomic variations in the structure and relations of the seminal vesicles and ampulla of the vasa. In a study of a large series of casts of the seminal vesicles and ampulla, many showed extremely convoluted tubules. Their very tortuosity may serve to protect them from infection. It is questionable whether digital massage is adequate to express the secretion completely from these extremely tortuous vesicles. Infection of the seminal vesicles, particularly the walls, has not been noted with any degree of frequency cited by the author. In an exhaustive histopathologic and clinical study by Hyams, Kramer and McCarthy it was shown that infection of the seminal vesicles is far less frequent and not as severe as that of the verumontanum, ejaculatory ducts and prostate. A factor in the persistence of urethritis, in some instances, may be the continued infection of the submucosal glands of Alberran, located at the posterior vesicle lip and internal sphincter. As a result of extension of some of these glands into the muscular layer of the urethra, in the presence of repeated infection from the urethra, glandular adnexa, or descending infection from the upper urinary tract, various prefibrotic changes occur, ranging from early change to terminal fibrosis. In his study of a hundred cases, it would be interesting to know whether the infection was primary or secondary and the exact clinical status. Cultural and microscopic examination of the prostatovesicular secretion for the gonococcus is necessary for the determination of cure, the presence of clumped pus cells is important.

Complement fixation tests for the gonococcus have not proved satisfactory, particularly when negative. In addition to these procedures, the cause for persistence of infection can be determined by the endo-urethral instruments of the McCarthy type. A clear demonstration of the urethra and vesical neck with or without water distention is essential for the localization and evaluation of the foci of infection. The criterion for the determination of the cure of gonorrhea, briefly, is the absence of the gonococcus.

DR. JOHN F. HOGAN, Baltimore. Some time ago I did some cultural work on the prostatic secretion, using hydrocele agar and testicular agar, and in many instances years after all clinical symptoms had subsided I found gonococci in cultures, in one man nineteen years later. I went into a very careful history with that man and he told me that he hadn't had any clinical symptoms of gonorrhea in the nineteen years. He came to me for relief of hypertrophy of the prostate. These organisms were morphologically and culturally gonococci. Of course the question comes up whether after all these years the organisms were virulent, that is, capable of producing the infection. That I don't know, but culturally and morphologically they were gonococci. I experienced no difficulty in differentiating *Micrococcus catarrhalis* and the gonococcus morphologically. Of course the meningococcus and the gonococcus look exactly alike morphologically, but I think all will admit that the urogenital tract would be a most unusual place to find meningococci.

MR. AMBROSE J. KING, London, England. I have been extremely interested in the comments, and I will take them in order. Dr. Wesson mentioned the question of sterility. I think he implied that if these persistent gonococcal infections are widespread, as I would have you believe, how is it that there are not more sterile marriages, more one-child marriages? We see a large number of sterility cases which we believe to be due to persistent gonococcal infection in the male and in which we find the gonococcus, but I think we see just as many cases in which the gonococcus is cultured in old standing infections, and yet the patient is married and has a family of children, although the wife is infected as well. As far as the complement fixation test is concerned, the claim that it is as useful in the diagnosis and treatment of gonorrhea as the Wassermann reaction is in the diagnosis and treatment of syphilis is not, in my opinion, an overstatement of its value. With regard to *Diplococcus crassus*, I know little or nothing about it. Of course, there are pseudogonococci described from time to time but I don't know that they enter into this discussion. Dr. Hyams said that a persistent urethral discharge was due usually to secondary infection, and one must agree with him. Yet in most of those cases an underlying gonococcal infection also is found. I was interested in his description of observations with the McCarthy panendoscope, and in what I saw in Dr. McCarthy's clinic the other day. I think this is a line on which more work may well be done in England. I think I have answered most of the points, and I hope to your satisfaction, and if I may be permitted a final comment it is that I have been impressed with the indifference in general of urologists toward the study of gonorrhea. The usual experience has been that the urologist has deputed the treatment of gonorrhea to his junior, or to his assistant who with his eyes fixed on the goal of his surgical ambitions considered his association with the disease a necessary but rather repulsive stepping stone to higher things. I think that, as a result, insufficient work has been done in the past and is being done on improvements in methods of diagnosis and treatment of gonorrhea. The tendency in England at present is to make a special subject of the study of syphilis and gonorrhea, and the specialist in venereology, as we call it, spends all his time and gives all his attention to these diseases. I think that in this way we may go some distance to solve the very serious problem which is responsible for innumerable individual tragedies and for considerable economic loss to the state. I am grateful for this opportunity of putting my ideas before you, and I thank you for the honor of this invitation. I bring greetings from mutual friends in London, and the assurance that the great work which has been done and is still being done by American urologists is a constant source of stimulation and enthusiasm to those who are working in the same field in Great Britain.

EXPERIENCES WITH THE GONOCOCCUS FILTRATE (CORBUS-FERRY)

AND OTHER FORMS OF INTRADERMAL THERAPY IN THE TREATMENT OF GONORRHEA

ROBERT E. CUMMING, M.D.

AND

ROBERT A. BURHANS, M.D.

DETROIT

The origin of antibodies has long been and continues to be a subject of theory and speculation. It is likely, however, that antibody formation is a widespread cellular function with all the varied types of body cells participating to some degree. The literature abounds with controversy, and untold effort has been directed toward the solution of this problem.

It has been generally recognized for some time that the skin is not merely a protective sheath for the body but an organ of vital importance in the production of immunity, recently there has been increasing recognition of this function.¹ The role of the skin in immunity has been demonstrated largely by animal experimentation, but we think that in the future it will become a factor in the clinical concept of infection and resistance. Review of the literature reveals that the intradermal administration of specific and nonspecific antigens has been concerned chiefly with the diagnosis and treatment of allergic conditions and tuberculosis until applied in our own field of endeavor.

Müller² in 1922 called attention to the fact that in gonorrheal urethritis of the male a marked increase in urethral secretion could be produced within a few hours by subcutaneous injection of small quantities of non-specific proteom. Corbus and O'Connor,³ inspired by the "antivirus" hypothesis of Besredka,⁴ found gonococcus bouillon filtrates to be unsuitable for urethral treatment but capable of stimulating the production of antibodies when injected intradermally.

It is not our purpose to explain nor are we capable of explaining the rationale of the form of treatment advocated by Corbus³ or to enlarge on his theories of immunity. We propose to relate our experiences of the past three years with the intradermal application of specific and nonspecific antigens in the treatment of gonorrhea.

Specific and nonspecific antigen therapy has occupied the attention of this assembly on various occasions. It is our impression that American urologists have largely given up the routine use of gonococcus vaccines, in spite of favorable reports that appear from time to time

The only convincing evidence that we ever have obtained as to the efficacy of gonococcus vaccine is embodied in the personally expressed opinions of surgeons of the British medical corps during the Great War, who were certain that routine use of vaccine in all cases of gonorrhea in the British army reduced complications, especially epididymitis, to a negligible minimum. Manufacturers do a large business in gonococcus vaccine, however, finding a continuous market for this commodity, in contrast to the vaccines for influenza and other more or less seasonal diseases. This indicates a persistent reliance on vaccines by the general practitioner, who cannot, like the specialist, gain impressions from large series of controlled cases. We believe that, if stock vaccines are used, the dosage should be very small and that the practice of giving large doses may account for many unfavorable results. Intradermal administration of stock gonococcus vaccines in the treatment of urethritis has in our hands accomplished nothing. To improve our knowledge of vaccine therapy we are considering the preparation of a large series of autogenous antigens by a method similar to that of Burbank⁶ in other infections. We are also attempting to evaluate the gonococcus complement fixation test as a control measure for further immunologic studies on gonorrhea.

In addition to gonococcus vaccines we have used certain other preparations intradermally in the treatment of gonorrhea and gonorrheal complications. Of these, which include gonococcus filtrate (Corbus-Ferry) gonococcus immunogens, sterile milk, a commercial "solution of lactalbumin" and sterile bouillon, only gonococcus filtrate has warranted prolonged consideration.

The solution of lactalbumin that we formerly used extensively by the intradermal method advocated by Müller² gave fairly effective but not uniform results and we concluded that the intracutaneous administration was superior to intramuscular injection of large doses. Sterile bouillon identical with that used in the preparation of the specific filtrate, given intradermally, resulted in a mild but definite systemic reaction without the specific local and urethral reaction observed after the gonococcus filtrate.

Gonococcus filtrate (Corbus-Ferry) is classed as a soluble toxin⁷ and is not to be confused with vaccines (bacterial suspensions), immunogens (bacterial washings), toxoids (solution of formaldehyde detoxified toxin) or serums (antitoxins). Whereas vaccines cannot be test-controlled, gonococcus filtrate can be standardized by skin test reactions in susceptible individuals and is adaptable for routine therapeutic use.

Our early studies were complicated by unstable and inactive lots of filtrate unwittingly furnished us. This fact goes far to explain adverse results reported by some of our colleagues who are unfavorable to the gonococcus filtrate.⁸ We promptly discovered in the light of previous experiences that concentrated gonococcus filtrate as well as certain other experimental lots did not give the expected local reactions or favorable progress in the disease. We have since relied on the active and stable material originally supplied. It is interesting that our best results have been obtained with filtrate stored at room temperature in contrast to the

same material stored at icebox temperature. We have been informed⁹ that the factors causing the deterioration have been eliminated and our own experience with later lots has verified this claim conclusively.

Gonococcus filtrate (Corbus-Ferry) has been used by us for a period of more than two and one-half years. We are presenting the records of 124 cases, in more than 100 of which injections were given as the sole treatment of the gonorrheal infection or as an adjunct to the usual therapy. Records are included of some patients to whom injections were given as a possible means of provoking renewed discharge to furnish material for smears and cultures. In addition, we shall discuss cases suspected of presenting gonorrhea in which the filtrate was administered as an aid in diagnosis.

One hundred and one of these patients were men, nineteen were women and four were girls. Of the entire series, only twenty-one patients were seen promptly after the appearance of a urethral discharge, and of these fourteen made up the clinic group. Four patients had a urethral discharge for from eight months to two years prior to coming under our care. Thirty-six patients related episodes of previous gonorrheal infection.

Certain advanced conditions or complications at the time the treatment was begun are important. Of the entire series, four had epididymitis, and active involvement of prostate and seminal vesicles. Two had balanitis, two acute gonorrheal arthritis, one a jaw involvement, and twenty-one active disease of the prostate and seminal vesicles. In two cases there was epididymitis present, without evidence of adnexal disease, in both cases there was rapid improvement.

One hundred and ten of this series were private patients and the remaining fourteen were treated in a small well controlled clinic by one of us (R. A. B.). We have considered it necessary to see our private patients frequently and regularly and, in addition to weekly injections of the filtrate, use a mild local therapy for anteriorly limited diseases and our routine treatment in instances of posterior involvement with adnexitis. Women were also treated locally and children received simple washes administered at home in addition to specific therapy.

The clinic group was treated successfully with only weekly injection of gonococcus filtrate, but in our opinion such a regimen is not compatible with private practice. The clinic patients were selected from a group presenting themselves promptly on the appearance of a urethral discharge, all were males, and all reported regularly, adhering strictly to advice pertaining to general living habits. The infection in this small group remained confined to the anterior urethra in all cases, and there were no complications or recurrences, other patients under recognized treatment at the same time and in the same clinic did not show equal progress.

We have been impressed by the fact that local reactions to gonococcus filtrate vary not only with the stage of infection but with the type of individual, two points being important enough to report because of sufficient repetitions during our long period of observation. One is that the general condition of the patient is related to his reaction, if he is robust, the reaction is less severe, although his infection may be most resistant, if feeble or "run down," the reaction is likely to be more severe. The other point relates to the color of the skin, the

blond individual shows a more intense reaction to a given dose

We grade the local skin reaction according to the degree of persistence of the skin wheal, which may remain as an intense red and slightly elevated area at the site of injection, and especially according to the extent of the reddened area surrounding the wheal. For convenience the reaction is recorded as "one-plus" if the redness is 1 inch (2.5 cm) in diameter including the wheal, "two-plus" if the extension is 2 inches (5 cm), and so on, "four-plus" meaning a 4 inch (10 cm) extension or more. Other than this, we have noted repeatedly a very definite inguinal adenitis on the side corresponding to the site of injection. Most of the latter are given in the thigh, so that the distribution advocated¹⁶ can be readily followed out, and also because injections in the arm are more likely to attract attention. This adenitis occurs only with a strongly positive reaction. We have seen only an occasional truly systemic reaction to gonococcus filtrate. We interpret a prompt fading of the wheal, lack of local soreness and lack of surrounding redness as a negative reaction.

Dosage of the earlier stock preparations ranged from 0.1 cc (2/20) to 1 cc, while the dosage of the aforementioned concentrated and unstable experimental lots was variable, depending on the degree of deterioration of the active principle. Our dosage range with the present stable and active preparation, as we now administer it, is from 0.1 cc (2/20) to 0.3 cc (6/20), and we have found no occasion to give larger doses as yet.

It has not seemed important to us to gauge the dose of gonococcus filtrate or the frequency of injection by the stage of the disease, by the intensity of symptoms or by the amount of urethral discharge. We have not practiced nor do we advocate Corbus's instructions¹⁶ of withholding injections until two weeks after the onset of the urethral discharge. Even though the immunity acquired by means of gonococcus filtrate (if such develops) is active, we can see no logic in withholding specific antigen therapy designed to foster such immunity. It has been our practice to administer gonococcus filtrate as soon as the diagnosis is established, and in some instances the discharge has ceased by the time of the second injection.

We have not seen the intensification of purely local symptoms described by Corbus,¹⁶ namely, increased urethral tenderness, swelling and inability to void, with more urethral pus. In contrast to this we have seen acute balanitis, with extreme swelling of the glans penis and local urethral bleeding, respond overnight to an injection of gonococcus filtrate. On the other hand, occasionally a patient who is making excellent progress will suddenly pass into a phase with quickly increasing symptoms and possible extension of the disease to the point, for instance, of fulminating adenitis, proving most recalcitrant to all treatment. We have been forced to conclude, therefore, that in some instances we supply the individual with excessive antigen. Yet, in a most severe case of urethritis, vaginitis and cervicitis, with vulval swelling and strangury, the response was phenomenal and organisms were never found after the time of first examination. So, therefore, we are in the habit of starting the injections of gonococcus filtrate as soon as the diagnosis of gonococcal infection is properly established. Also we continue its use for a period, even if organisms do disappear, although usually the repeatedly negative smear is our signal for interrupting the specific treatment.

The number of injections of gonococcus filtrate ranged usually from seven to ten. One patient was given seventeen injections, and one thirteen. The average number of injections for private patients was 5.3, and for clinic patients 7.

The period of time in which organisms were found roughly corresponds to the time of active urethral discharge. This varied in the group of private patients from one day to sixteen weeks and, disregarding one or two instances in which organisms were found only once, averaged five weeks. In the clinic group the range was from three to seven weeks, with the average likewise five weeks.

Gonorrheal vaginitis of the children included in this series showed a phenomenal response to gonococcus filtrate. We hope to continue our studies and endeavor to bear out these favorable impressions. Complete cessation of vaginal discharge occurred within from one to ten weeks. In passing, we should state that the dosage of gonococcus filtrate was lessened according to the age of the child in each instance.

Twenty-two men are still under treatment for adnexitis and eight women for cervicitis. The four little girls are under inspection for any possible return of the specific vaginitis.

We state boldly that except for stubborn adnexal involvement in the male, which is really an extension and not a complication, we have seen no complications and fewer recurrent infections after gonococcus filtrate. Naturally we believe this is partially circumstantial and that complications will occur in cases treated with this or any other preparation. In our opinion gonococcus filtrate is a means of reducing the number of complications as well as attaining a safer postinfection period for victims of gonorrheal infection.

REPORT OF CASES

The following abstracts serve to illustrate our text.

CASE 1—C (clinic), a man, aged 24, admitted, Feb 21, 1933, was exposed seven days previous to examination. Dysuria started on the fifth day and a urethral discharge on the sixth day. Examination showed a profuse urethral discharge. A smear was positive for gonococci. The first injection was 0.5 cc of gonococcus filtrate. There was a four plus reaction with increased urethral discharge and adenitis. The patient was given five weekly injections ranging from 0.5 to 1 cc. There was no discharge after the fourth injection and no reaction to the fifth dose. There were no complications. The prostate was normal. The second glass of urine remained clear. The patient was examined two months after the last injection of gonococcus filtrate, all examinations were negative and there was a negative reaction to 0.5 cc. of gonococcus filtrate (provocative).

CASE 2—S, a man, aged 20, admitted to the hospital, Sept 8, 1933, had had acute urethritis three and one-half months previously, with a discharge. The diagnosis was urethritis and acute parotitis. He was given stock gonococcus vaccine. There were no irrigations or injections. The discharge was thin and watery at this time but has never ceased. A sudden rise of temperature to 104 F, with swelling of the right mandible and parotid region, was followed by swelling of other joints but no redness or inflammation. A consultation with us, September 19, resulted in a diagnosis of arthritis of the right maxillomandibular joint. Examination was positive for urethritis and vesiculitis. Vas puncture and gonococcus filtrate were advised. Vas puncture was done, September 20, relieving the arthritis. Gonococcus filtrate was started with a 0.5 cc. dose. There was a moderate reaction with increased purulent urethral discharge. Urethral injections were started. There was only a "morning drop" after five days. The second dose, 0.75 cc. of gonococcus filtrate, gave a severe reaction and more

discharge for two days. He left the hospital, September 28. Daily office visits followed with irrigations and massage of the prostate, which was very large, soft and boggy, with four plus pus in the secretion. This routine treatment was continued with weekly injections of gonococcus filtrate, of which he had nine doses, with only a mild return of the discharge after the first five injections. The arthritis subsided entirely after the first two injections. No residual disease was seen in the joints. He was last examined, May 10, 1934. There was a mild residual prostatitis present.

CASE 3—Miss J, aged 28, admitted, Sept. 20, 1933, had a profuse vaginal discharge and frequency of urination. She had been unexpectedly and unintentionally intoxicated ten days previously, with forced coitus. She had been uncomfortable ever since. She noted the discharge only the last five days. Examination showed pus from the urethra and Skene's ducts, and very angry vaginitis. The cervix was ulcerated, with a gross purulent discharge. A stained smear was positive for gonococci, the urethra and vagina were involved. The patient was given 0.3 cc. of gonococcus filtrate. Mercurochrome was applied to the cervix and urethra. She was given five weekly injections of gonococcus filtrate, ranging from 0.3 to 0.5 cc. No positive smear could be obtained after the first injection of filtrate. After the first week she was treated vaginally twice a week and with gonococcus filtrate once a week, late provocative filtrate injections were negative.

CASE 4—P, a man, aged 40, admitted Feb. 8, 1934, complained of a chronic urethral discharge, pyuria, frequency and nocturia. He had had an acute gonorrheal infection in October 1933. The discharge started seven days after exposure and he was treated elsewhere immediately. An "acid drug, and hypodermics" were given daily, then on alternate days. He did not improve, so he changed his physician in November. He was given nineteen treatments with mild silver protein. He complained of severe rectal pain and frequency requiring opiates. He went to a third physician with a "sore rectum and back-ache", he was given liquid petrolatum and urinary sedatives, which relieved the condition somewhat. Three days before he saw us, the discharge began again, he saw his physician, who gave him a different drug, causing extreme swelling of the penis, which was present when he consulted us. On examination, a smear showed many pus cells, a few intracellular diplococci and many extracellular diplococci. He was given 0.3 cc. of gonococcus filtrate, which made him very uncomfortable and gave a four plus local reaction but resulted in a reduction of edema and no discharge on the following day. The second day the temperature was 102 F, the edema was gone and the prostate was swollen and tender. He was given four weekly doses of gonococcus filtrate, ranging from 0.2 to 0.3 cc., there was no later discharge or edema. After three weeks the prostate was small, but the secretion showed three plus pus. The fourth week the prostate was small and fibrosed and the secretion showed pus two plus. There was no reaction to gonococcus filtrate, April 1, 1934, and only an occasional pus cell in the prostatic secretion.

CASE 5—G, a man, aged 34, admitted, Feb. 10, 1934, complained of frequency, dysuria, rectal pain and a discharge. He had a history of gonorrheal infection in November 1933, with frequency and burning on urination since. In December 1933 he had severe rectal pain lasting several days. One week previous to admission a smear was found to be positive, he was given an injection (elsewhere). Thirty hours later he had a severe chill, fever and sweats, these recurred for several days, with a temperature up to 102 F. Associated was a return of the rectal pain for the past five days and a discharge for the past week. There was frequency to every half hour. He was given 0.2 cc. of gonococcus filtrate, the reaction was three plus, with less discharge the following day and only mucoid discharge on the third day. The prostate was tender and firm. The fourth day the prostate was small but the entire rectum was tender. The fifth day very acute prostatitis was present bordering on abscess. He was hospitalized. The fever subsided and the prostate improved. There was no discharge. On the ninth day he was given 0.2 cc. of gonococcus filtrate, with a mild local reaction. The prostate was much improved and he was discharged from the hospital. He was given three

more weekly doses of 0.3 cc. of gonococcus filtrate. There was no discharge and local reaction. The prostate secretion was two plus before the last injection of gonococcus filtrate and four plus following it. He was still being treated for mild prostatitis, May 1, 1934.

CASE 6—B, a man, aged 31, admitted, Jan. 5, 1934, had had a gonorrheal infection eight years before, with mild stricture and prostatitis. An acute gonorrheal infection, Oct. 19, 1933, was treated by a physician with daily injections of 2 per cent strong silver protein until Jan. 2, 1934, then with neosilvol. A smear, January 2, was reported negative. The patient was referred to our office. A very moderate urethral discharge was found. It was positive, with intracellular gram negative diplococci. The prostate was large, hard and fixed, with definite fibrosis. Seminal vesicles fibrosed at the bases. Pus was four plus. He was given 0.2 cc. of gonococcus filtrate, followed by a severe reaction with adenitis and a profuse discharge, the condition has continued with a discharge, decreasing weekly, followed by increase and severe reaction after each injection of gonococcus filtrate. The patient has had thirteen injections in a dosage of from 0.2 to 0.3 cc., with routine treatment, massage and dilation of the urethra. Owing to continued urethritis, four endoscopies have been done, with 10 per cent silver nitrate solution applied directly to the ulcerated areas in the posterior urethra. The patient is still under treatment. The prostatic smear is positive. Diathermy to the prostate has improved the condition so that cure was apparent at the examination, June 1. This case has been resistant to gonococcus filtrate treatment and the record is given to indicate occasional failure of this additional aid in treatment.

CASE 7—C, a man, aged 32, admitted, Feb. 8, 1934, was exposed nine days previous to examination. There was no dysuria or frequency. Five days after exposure, after drinking to excess, he passed bloody urine. Four days later he noted a white discharge, a smear showed many pus cells and gram negative intracellular diplococci. He had had a gonorrheal infection in 1917 and in 1918. In his first treatment with us he was given 0.2 cc. of gonococcus filtrate, the reaction was four plus, in four days the discharge disappeared. At this time he was given 0.2 cc. of gonococcus filtrate, with no local or general reaction. Seven days later 0.3 cc. of gonococcus filtrate was given, with no reaction, discharge or organisms. He was treated by massage and washes. Six weeks after onset, after missing some treatments, he had a "morning drop", repeated smears were negative. He was having regular coitus and was drinking. The prostatic secretion was one plus pus and the smear was negative. Eight weeks later he noted that the meatus was sealed. He was given 0.2 cc. of gonococcus filtrate as a provocative test, which gave a severe three plus reaction and a positive smear. The discharge disappeared in two days. The prostate responded further under treatment and no organisms could be found. One week later he was given 0.2 cc. of gonococcus filtrate, with a three plus reaction. June 1, the prostate was normal but the patient is still under observation. Gonococcus filtrate injection on this date gave a negative reaction.

CASE 8—F, a man aged 28, admitted in November 1933, had a profuse chronic urethral discharge. A smear showed positive intracellular gram-negative diplococci. He had contracted gonorrhea from five to six years previously and had never been cured, he had chronic prostatic and seminal vesicular involvement. The present discharge started a few days before admission. He was given 0.2 cc. of gonococcus filtrate, it gave a four plus reaction with right inguinal lymphadenitis, the discharge decreased after the fourth day. He was given six weekly doses of gonococcus filtrate ranging from 0.2 to 0.4 cc. There was no discharge after the fourth dose except a profuse discharge for one day after the fifth injection. There was no reaction to the sixth injection. The patient returned four months later with an acute urethral discharge after a definite exposure. The smear was positive. He was given 0.1 cc. of gonococcus filtrate, the reaction was four plus, with adenitis. Twenty-four hours later there was very little discharge, and none after three days. The patient was still under observation, June 1. During this period routine treatment for posterior urethral involvement and adnexitis was given.

COMMENT

Early in our studies we were impressed with the possibilities of gonococcus filtrate as a provocative and diagnostic agent. We have used gonococcus filtrate in twenty-one cases as a diagnostic test or to provoke an increased specific urethral discharge as well as to locate dormant infections of the adnexa. We are not aware whether others have used gonococcus filtrate as a provocative agent. Our adoption of such a procedure has developed from the fact that a large part of our practice concerns patients who have been under treatment for varying periods elsewhere, coming to us in consultation or because of dissatisfaction. We felt that a relatively large dose (from 0.1 to 0.4 cc) of gonococcus filtrate might activate dormant organisms for a short period, enabling one to make an accurate diagnosis, this supposition has been borne out occasionally. We have come to be fairly sure that the organisms are not present if the local reaction is negative and nonproductive of discharge or other returning symptoms.

In all twenty-one cases repeated smears were negative prior to the use of gonococcus filtrate, and the patients were free from gonorrheal infection as determined by the diagnostic measures ordinarily at our disposal. Six were known to have been infected with gonococci, others were suspected of having dormant gonococcal infections of the adnexa, and a few presented themselves for examination following known exposure. One man was under treatment for prostatitis, his reaction was strongly positive after a period of several months without organisms, and the latter appeared in a fresh urethral discharge and in the secretion from the adnexa. The injection in another case, eight months after known presence of organisms, gave no reaction. Likewise, an injection in one case two years after organisms had disappeared gave no reaction. In the other three cases, in which infection was known to have occurred, while organisms were found, the local skin reaction was positive, the increase of symptoms subsided with continued use of the filtrate and other appropriate treatment. In many sluggish cases the intradermal injections have caused a transient acute phase that is a powerful stimulus to the patient in the way of compelling more careful attention to instructions as to self care and faithfulness to treatment.

To control the use of gonococcus filtrate as a diagnostic provocative agent we have given injections to several individuals who were known never to have had gonorrhea, in none was there a positive diagnostic reaction or evidence of a urethral discharge. We have also administered, intradermally, plain bouillon identical to that used in the preparation of gonococcus filtrate, to patients both with and without known infection. Other than mild, definite systemic reactions attendant to such injections, we have observed nothing suggestive of the reactions just related.

SUMMARY AND CONCLUSIONS

Gonococcus filtrate (Corbus-Ferry) intradermally is the only antigen of the several we have tried that seems to offer a specific aid in the treatment of gonorrheal infection and complications. No attempt has been made to explain the rationale of intradermal medication or to establish the role of the skin in body immunity.

We have demonstrated that the filtrate can be used alone in the treatment of gonorrhea. It is our impression that gonococcus filtrate is most serviceable as an adjunct to mild local treatment. As pointed out, the

filtrate is indicated in acute and chronic gonorrheal infections of men, women and children. It has been used freely in all types of complications and, in our opinion, has some virtue in amelioration, although other treatment, not so important in simple urethral involvement, is of prime necessity.

We have not followed the recommendation of Corbus⁶⁶ but have used the filtrate freely in all stages of the infection and complications. We have departed from the recommended dosage scheme by giving not more than 0.1 cc of filtrate (children should receive from 0.05 to 0.15 cc of filtrate), increasing weekly by from 0.05 to 0.2 cc (1/20-4/20), depending on the local skin, regional lymph gland, and systemic reactions as well as on the character of urethral discharge and the states of the infection.

Complications are today, as they have always been, of greatest importance in gonorrhea, late and unexpected transmission of the disease, sterility in both sexes, and the determination of safety in marriage are questions peculiarly in the domain of the consulting urologist. The determination of cure in gonorrhea has always been a difficult problem. We believe that our use of gonococcus filtrate in large doses (from 0.1 cc to 0.4 cc) as a diagnostic or provocative agent to demonstrate dormant infection is a milestone in progress toward the ultimate cure of obstinate gonorrhea.

1553 Woodward Avenue.

ABSTRACT OF DISCUSSION

DR. BUDD C. CORBUS, Chicago. Two years ago when I presented before this section a new method of treating gonorrheal infections in men, women and children, the experience of only a few collaborators was available. Since that time, however, more than a hundred urologists here and abroad have had an opportunity to use and evaluate this method. Last year the clinical experimental work was delayed because of the lack of potency of the filtrate. This has been corrected and there is available a bouillon filtrate the average minimum dose of which is only six twentieths of a cubic centimeter with a potency that is absolutely guaranteed. Whole gonococcus vaccine has long been recommended as an aid in the treatment of gonorrheal infections. If one takes the trouble to stain a given ampule, not a single whole gonococcus is visible, they have all autolyzed. However, a few favorable results have been reported when fresh preparations have been used. These were not used intradermally, however. The histiocytic elements in the skin are capable of being stimulated by both specific and nonspecific proteins. In the gonococcus bouillon filtrate there is a soluble specific toxin (protein) that is easily assimilated by the cytoplasm of the histiocytic cells, which in turn produce a specific antibody capable of influencing the infection in whatever part of the body it may localize. This specific antibody accumulation within the blood has been demonstrated time and again after a cure has been obtained by the complement fixation test for gonorrhea whereas in the beginning of the infection, unless severe complications are present, the complement fixation test is invariably negative. The use of the bouillon filtrate as a diagnostic procedure is new to me. However, I can see that this method of producing a urethral discharge might be productive of positive results in making a diagnosis. The question has repeatedly been asked: Will this gonococcus bouillon filtrate produce an immunity sufficiently capable of protecting an individual if exposed to infection? This experiment has never been tried, although I am anxious at some future date to see whether it is not possible to vaccinate an individual and later see if he can be inoculated with the gonococcus. When I first used the bouillon filtrate, too large a dose was often given and the reaction in the urethra was sometimes severe, causing tenesmus and inability to void. With the standardization of dosage as suggested by both Drs. Cumming, Burhans and myself, and with the filtrate that is available now, this complication should not occur. Biologic therapy is

precarious Robust individuals react less severely to intradermal injections than those who are feeble or run down. However, in my experience, often a cadaverous looking individual builds his immunity faster than his robust neighbor. I have never noticed the susceptibility to blonds over brunettes. The idea of grading the size of the wheal as a guide to future dosage is admirable. Irrespective of the size of the wheal, I have not found it advantageous to continue the use of the toxin after the gonococcus has been absent from the urethra for two weeks.

DR. ROBERT E. CUMMING, Detroit. As Dr. Mathe of San Francisco was to have read a paper on this subject, I should like permission to quote two paragraphs from a letter recently received from him: 'It is my opinion that filtrate is of great benefit in the treatment of acute gonorrhea, particularly if used shortly after the appearance of the discharge. If employed during the first five days after its appearance, it will often abort the disease. In those cases in which the disease is not aborted, it seems to lessen the occurrence of the usual complications, consisting of posterior urethritis, acute prostatitis with and without abscess formation, epididymitis, arthritis, pyelonephritis and cardiac disease. I have used the filtrate according to the dosage outlined by Corbus and Ferry. It has given splendid results in more than 100 acute cases, and I am very enthusiastic in its use. In chronic cases of prostatitis and seminal vesiculitis complicated by arthritis it also gives good results. The gonococcus bouillon filtrate of Corbus-Ferry constitutes a very active definite antigenic agent, and if those who feel that they care to use such an agent have found that this particular preparation has not been successful in their hands I believe it is solely because they have unwittingly received inactive preparations, which can be included among those lots I referred to in the text as being unstable and variable.'

PRESENT STATUS OF TETANUS, WITH SPECIAL REGARD TO TREATMENT

REPORT OF FURTHER CASES FROM THE MASSACHUSETTS GENERAL HOSPITAL.

RICHARD H. MILLER, M.D.

AND

HORATIO ROGERS, M.D.

BOSTON

The prevention of tetanus has reached a substantially sound and reliable status, but the treatment in general is hardly more satisfactory than it was when Hippocrates handled the cases at the battle of Salamis, or when, centuries later, Frederick May advocated the use of infusions of tobacco by rectum. Our purpose in this paper is to add another series to the previously reported 116 cases from the Massachusetts General Hospital,¹ bringing the total to 149, and to deduce therefrom such conclusions as we may, also to review the current literature.

The modern conception of tetanus is that it is a disease caused by the toxin elaborated by the bacilli. The toxin circulates in the blood stream and is picked up by the motor nerve end plates and thence transmitted up the axis cylinders and perineural lymphatics till it reaches and becomes firmly fixed in the motor cells of the central nervous system, there causing irritative phenomena which result in tonic and clonic muscle contractions.² In the cases of general tetanus, or tetanus descendens (the more common form), the muscles with the shortest motor nerve trunks, the masseters, are first

affected, then the muscles of the neck, thorax and back. This form predicates the circulation in the blood stream of a considerable amount of toxin. In that rare form local tetanus, or tetanus ascendens, the toxin is not to any marked degree present in the general circulation, rather it involves, at least at first, only the motor nerves to the affected part, resulting in irritation of the motor cells of the anterior horns of the cord, with subsequent local spasm, tonic or clonic. By the nature of the process it can be reasonably assumed that the local form will be less virulent and fulminating than the general type. The largest series of cases of local tetanus is that of the British army, reported by Sir David Bruce,³ he found 201 local cases in a total of 1,458, a high percentage which was doubtless due to the universal use of prophylactic antitoxin in the army.⁴

That tetanus bacilli are frequently normal inhabitants of the intestinal tract of man, as well as of animals, is well known. Tenbroeck and Bauer⁵ found B. tetani in the stools in twenty, or 34.7 per cent, of seventy-eight persons, and all twenty-six were found to contain appreciable amounts of tetanus antitoxin in the blood. This brings up the interesting suggestion, which they make, that such persons may have a potential immunity to tetanus, and such immunity may, to a degree, account for some of the very mild cases that one sees or, indeed, may furnish an absolute protection against this infection.

Since the previously mentioned phenomena of the distribution and later fixation of the tetanus toxin in the motor cells of the central nervous system are now appreciated, one is led at once to a consideration of the exact relation of the affected motor cells to the circulating fluid of the subarachnoid space, or cerebrospinal fluid, because it has been generally accepted that the introduction of the antitoxin into the subarachnoid space would doubtless afford a sound and scientific method of therapy. As a matter of fact, this assumption is without any theoretical support and with little clinical basis. The recent articles on this disease that have come to our attention have stressed the good or bad clinical results of the intraspinal use of the antitoxin, without analyzing the physiologic backgrounds.

The cerebrospinal fluid is elaborated largely by the choroid plexus, though there is evidence to show that possibly the perivascular spaces and ependymal cells lining the ventricles may produce a certain amount.

The absorption of (or fate of) the cerebrospinal fluid has been studied intensively by Weed and others.⁶ Weed used a series of experimental animals, injecting into the subarachnoid space, at normal intraspinal pressure, a ferrocyanide-citrate mixture, immediately fol-

lowing this with introduction into the circulation of solution of formaldehyde, with enough hydrochloric acid to precipitate the ferric ferrocyanide (prussian blue granules), which were then studied both macroscopically and microscopically. According to Hughson⁷ his results were, in brief, as follows

In the replacement experiments the precipitation of the prussian blue was wholly localized within the subarachnoid space, and the nervous tissue was absolutely free from coloration, these facts being shown both grossly and microscopically. There was also no penetration of the perivascular spaces. The granules, however, were traced directly into the arachnoidal villi, projecting into the basilar dural sinuses, particularly the cavernous sinuses. Furthermore, the granules could be seen passing through the mesothelial cells, capping the villus and through the endothelial cells of all the dural sinuses.

Weed said in part

It seems fair to assume that the absorption of the cerebrospinal fluid is a twofold process, being chiefly a rapid drainage into the great dural sinuses and in small part a slow indirect escape into the true lymphatic vessels.

In all this conclusive work there is nothing to suggest, even remotely, that the cerebrospinal fluid, or any foreign protein which it might contain, could possibly be brought into contact with, or penetrate, the motor nerve cells in the substance of the nervous tissue, the cells that contain the tetanus toxin.

The introduction into the blood stream of a foreign serum, or antitoxin, plus the simultaneous intravenous injection of a large amount of 0.45 per cent sodium chloride solution (a hypotonic solution just strong enough to avoid hemolysis), plus continuous lumbar drainage, produces a great increase in the formation of cerebrospinal fluid, or drainage of fluid from the blood into the subarachnoid space. This is called "forced drainage" and has been employed by Kubie⁸ in the treatment of poliomyelitis, and by Fremont-Smith, Putnam and Cobb⁹ in the treatment of multiple sclerosis. Kubie says

Forced drainage may be used either (a) alone or (b) as a vehicle for the intravenous administration of serum under optimal conditions for the transfer of antibodies from the blood stream to the central nervous system or (c) as a method of preparing the central nervous system for a subsequent subarachnoid injection of serum.

The use of intraspinal injection of antitoxin plus simultaneous intravenous hypertonic sodium chloride has been suggested. We have employed the intravenous administration of antitoxin plus lumbar drainage (not continuous) in one case of tetanus with no appreciable effect.

A vast amount of work has been done on this interesting subject, though not dealing directly with tetanus antitoxin, and the sum and substance of it all is that a foreign protein, such as antitoxin, introduced into the subarachnoid space, will be almost entirely discharged into the dural venous sinuses through the pacchionian granulations and a very small portion may be absorbed by the subarachnoid vessels, in neither instance is there the slightest reason to suppose that antitoxin, so introduced, can get directly into contact with or within the affected motor cells. On theoretical grounds therefore

there is absolutely no basis for the intraspinal use of tetanus antitoxin, and clinical observations go far to support this thesis.

The comprehensive classification of tetanus, given by Courtois-Suffit and Giroux,¹⁰ may be presented here to advantage

- 1 Classic forms (descendens)
- 2 Abnormal forms
 - A Splanchnic (after abdominal operations)
 - B Cephalic (wound of head)
 - (w) Nonparalytic
 - (r) Paralytic (with facial paralysis)
 - (y) With oculomotor paralysis
 - (z) With hypoglossal paralysis
 - C Unilateral
 - D Tetanus of limbs (local)
 - (r) Monoplegic
 - (y) Paraplegic
 - E Abdominothoracic
 - F Attenuated form with long incubation

The abnormal forms, particularly the local type, are most likely to develop in those cases in which a prophylactic injection of antitoxin has been given.

Numerous articles on tetanus may be found in the literature, and brief reference to some of these will here be made, under appropriate headings.

TYPES OF TETANUS

Tetanus Neonatorum—This occurrence is not uncommon in China and the other countries of the East. Bratusch-Marrain¹¹ has seen twenty-six cases in Graz, especially in the older portions of the city, he recommends for treatment magnesium sulphate and chloral, as well as antitoxin both subcutaneously and intraspinally.

"Vaccination Tetanus"—Tetanus following vaccination against smallpox has always caused very serious concern among the medical profession, and it is interesting to note that in most cases the contaminating infection with B tetani has apparently developed some days after the vaccination, as an accidental occurrence. This fact is stressed by Armstrong,¹² who collected ninety-eight cases from thirty-two states and the District of Columbia. He advises very small areas of vaccination ("insertions") and no subsequent covering pads. Klemmer and Crosland¹³ found ten cases of postvaccination tetanus in ninety-six cases in Lancaster, Pa.

Tetanus Following Clean Operation—Several years ago there was an outbreak in Madrid of about twelve cases of postoperative tetanus, thought to be due to contaminated suture material (catgut). The contamination through intestinal contents and spores on the skin has been studied by Meyer and Spector.¹⁴

Erdman¹⁵ and Muller¹⁶ each report such cases. We are indebted to Dr. William F. Dolan¹⁷ for permission

to refer to three cases, following clean operations, which were seen in consultation by one of us (R H M) and several others. These cases were moderately severe, and all ended in recovery after adequate treatment. The exact source of the contamination was never determined, but it was thought to be the catgut.

TREATMENT

Hughson,⁷ in 1924, gave the opinions of eleven different authors and the British Tetanus Committee on the use of antitoxin, all advised its use, with various adjuncts, but there was no unanimity of opinion in

TABLE 1—Outcome with Regard to Portal of Entry

regard to the intrathecal route. Some were highly in favor of it, some equivocal, none definitely against it. Huntington,¹⁸ whose splendid article every student of the subject should read, and Cooper¹⁹ are lukewarm in their advocacy of antitoxin. Graves²⁰ recommends large doses but does not think that the intraspinal administration is of any especial value. Klemmer and Crossland¹³ found a distinctly higher mortality in those having intraspinal antitoxin than those who did not. Wainwright,²¹ in a masterly review of the subject, says "Intraspinal injections are harmful, increase mortality, and should be abolished. Antitetanus serum is not useless. The efficiency will depend directly on the promptness with which it is given. The best sedative is chlorbutanol (chloretone)." Higgins and Harrison,¹ who have already reported and discussed four of the cases (children) included in our series, advocate the employment of smaller doses of antitoxin, favor the use of tribrom-ethanol as a sedative, and say "It would

TABLE 2.—Effect of Length of Incubation on Mortality in Thirty-Three Cases

Incubation Period	Cases	Mortality
1 From 1 to 10 days	13	76.9%
2 Eleven days or more	17	23.5%
3 Unknown	3	33.3%

seem then that, in giving tetanus antitoxin intraspinally, there is no added therapeutic value and may result in greater discomfort to the patient and perhaps some injury to the nervous tissue by increasing edema of the brain and spinal cord."

TETANUS AT THE MASSACHUSETTS GENERAL HOSPITAL

In a previous paper by one of us²² there were recorded 116 cases of tetanus, seen at the Massachusetts

General Hospital from 1872 to 1921, inclusive. The total mortality in the series was 69.9 per cent.

From 1900 to 1909 (inclusive) there were eighty-nine cases, with a mortality of 65.1 per cent, from 1910 to 1915 (inclusive) there were forty-five cases, with a mortality of 57.8 per cent, from 1916 to 1920 (inclusive) there were twenty-five cases, with a mortality of 52 per cent, and in 1921 there were five cases, with a mortality of 40 per cent. From 1922 to 1933 inclusive the diagnosis of tetanus was made thirty-three times at the Massachusetts General Hospital. Fifteen patients died and eighteen recovered, a mortality rate of 45.5 per cent for the whole group.

Diagnosis—The diagnosis was obvious clinically in all but one case²³ in which there were also signs suggestive of meningitis. In only one case was the diagnosis confirmed by culture of the bacillus from the wound. Usually the portal of entry was healed by the time the patient came under observation. Autopsy was done in eight of the fifteen fatal cases.

Portal of Entry—It was often extremely difficult to get a story of the injury from which the disease started. In four cases no portal of entry could be traced. These all happened to be cases which recovered. The location of the portal of entry in the remaining cases does not seem significant, with the possible exception of hand lesions, five recovering to only one dying.

TABLE 3—Abdominal Rigidity

	Recoveries	Fatalities
Abdomen soft	1	3
Abdomen rigid	14	6
	(3 "boardlike")	(1 "boardlike")

Symptoms—The early symptoms were often rather vague and nondistinctive. General malaise, lame muscles of the back, headache, sore throat, facial asymmetry, and involuntary grimacing, for example, did not offer any clue to the true condition. These symptoms were rapidly followed, however, by discomfort in the jaws, inability to open the mouth, stiff neck, and finally convulsions. Although the incubation period in some cases had a duration of several days or weeks, once the symptoms appeared they developed in a few hours. There seemed to be no demonstrable relationship between the nature of the first symptoms and the severity of the disease.

Incubation Period—Of course, in cases in which the portal of entry was not known the incubation period could not be determined, but table 2 shows the relationship between the prognosis and the incubation period where known.

Although the figures in table 2 serve to confirm further the already familiar generalization that a short incubation period tends to be a good omen, it is well to note that this is only a tendency and that, in this series, not every case with a short incubation period ended fatally, and not every case with a long one went on to recovery.

Abdominal Rigidity—A sign that is not usually stressed in descriptions of tetanus was present a surprising number of times in this series. In nine of the thirty-three cases no note was made regarding the abdominal wall. Of the remaining twenty-four, how-

ever, twenty showed abdominal rigidity, referred to in four instances as "boardlike," and only four presented soft abdominal walls. This is mentioned here not because of any possible significance it may have in the course of the disease but to point out the danger of being misled into a diagnosis of some acute intra-abdominal lesion in a case of tetanus in which the other symptoms are not particularly striking. With regard to the possible significance of abdominal rigidity in tetanus, table 3 is suggestive, at least on first sight.

We are not prepared to draw any conclusions from this distribution of results, however, beyond the obvious one that among the fatal cases were many patients too sick to be thoroughly examined.

Temperature and Leukocytosis—Among the patients who recovered, the temperature rarely was higher than 103 or lower than 101, and the average temperature was 102.8 F. The average white blood cell count for this group was 12,500, five patients having white blood cell counts below 10,000, and one as low as 4,000.

The fatal cases usually presented a much higher temperature, which as a terminal event often went above 105 and in two instances as high as 108, the average being 105.6. The white blood cell count, however, did not show a commensurate increase, the average being only 18,500. Not one was below 15,000, however, in the group of fatal cases.

Clinical Course—The classic course of the disease has often been described and will not be repeated here, but a few significant figures will be mentioned. The average time from onset to death in the fatal cases was three days. In only one fatal case did the patient live as long as ten days, and eight patients (54 per cent) died within two days of onset.

In marked contrast is the average duration of 3.2 weeks from onset to recovery in the nonfatal cases. The longest time was six weeks and the shortest two weeks.

TREATMENT

It will not be possible to record all the details of treatment. Typical methods used will be described and the subject discussed in a general way.

Sedatives—Many of these patients were already having convulsions on admission to the hospital, so that the most urgent problem was that of sedatives. A typical picture is as follows (case 25): "He lies still and half asleep, but on any sensory stimulus becomes cyanotic, with neck hyperextended, jaws set, spasm of the whole body, and loss of sphincter control." Another typical picture is from case 27: "Lies quietly in bed until someone enters room, when suddenly has severe spasm with marked risus sardonicus and great apparent pain. Subsides immediately, but this is repeated at each noise or movement of visitors." Still another is from case 22: "In emergency ward he went into opisthotonos, was covered with sweat, and was apparently suffering indescribable agonies."

The agents most often used were phenobarbital, 10 grains (0.6 Gm) by rectum or 3 grains (0.2 Gm) by mouth, morphine, $\frac{1}{4}$ grain (0.016 Gm) subcutaneously, chloral, 30 grains (2 Gm), paraldehyde, 5 cc, sodium amytal, 12 grains (0.8 Gm), and tribromethanol, from 80 to 100 mg per kilogram of body weight. Two patients were given repeated primary ether anesthesia to control extreme spasms. Large amounts of sedatives were sometimes needed. Patient 21, a man, aged 45, who made a complete recovery,

was given chloral, 75 grains (5 Gm), morphine, $\frac{3}{4}$ grain (0.05 Gm), phenobarbital, $7\frac{1}{2}$ grains (0.5 Gm), and paraldehyde 20 cc, all in the space of thirty-six hours. Tracheotomy was done three times in the vain hope of making respiration easier.

Antitetanus Serum—Only one of the patients (case 12) in this series had received prophylactic antitetanus serum before admission to the hospital. As soon as the diagnosis was made, every patient was given large doses. In most instances the serum was administered by several routes. Two patients had intramuscular injections alone, and five had only intravenous injections. Four patients had serum injected into the tissues at the suspected portal of entry in addition to some other method of administration. Eleven patients received intraspinal injections in addition to other routes. Six of these recovered and five died. The intravenous route was used the most often (thirty cases), intramuscular next (twenty cases), intraspinal next (eleven cases) and local least often (four cases). Table 4 shows how

TABLE 4—Methods of Administration

Method of Administration	Number of Recoveries	Number of Fatalities	Total

these different methods of administration were combined, and how the individual methods were divided between the fatal and nonfatal cases.

So many other factors influence the outcome of each case that it would be futile to try to evaluate the different combinations of methods of administering serum from these tables. They do serve to show, however, that no one method stands out as greatly superior in results to the others, and that those patients treated without spinal injection did at least as well as those treated with it. There is no reason to infer that only the sickest patients were selected for intraspinal injections. On the contrary, one of the most serious practical objections to this method is its technical difficulty or impossibility in the presence of spastic hyperextension.

The largest amount of serum used in a single case was 310,000 units. The average amount in the fatal cases was 112,000 and in the nonfatal cases 160,000. The difference is merely a reflection of the shorter period of time during which the fatal cases were available for treatment.

Serum Reaction—Patient 12 proved to be hypersensitive to horse serum on the routine skin test, and it

is interesting to note that this was the only patient who had received prophylactic antitetanus serum. During the process of desensitization on the first day he reacted by flushing and blanching, sweating, nausea, transitory urticaria, cyanosis and mild respiratory difficulty. After the first day large doses of serum were administered intravenously and intramuscularly without incident.

Ten other patients showed serum reactions of various kinds and degrees, making a gross incidence of 33½ per cent in the whole group. These reactions were of two distinct types. The first type consisted of symptoms immediately after an injection, varying from a transitory rise in pulse to an alarming degree of collapse. The other type consisted of urticarial rash coming on several days after a serum injection. Patient 15 demonstrated both types of reaction.

The important thing is that the dangerous anaphylactic phenomena, though occasionally suggestively shown in from three to five days after the initial injection, do not usually occur until after about ten days, or later. After the lapse of ten days from the institution of the serum treatment, further administration must be carried out with caution.

The serum sickness, characterized by such conditions as urticaria and joint symptoms, develops on an average of ten days after the first injection and can be controlled by subcutaneous injections of epinephrine.

COMMENT

The mortality in cases of tetanus at the Massachusetts General Hospital has decreased, though never below 40 per cent, which was the figure in five cases in 1921. From 1922 to 1933 inclusive the mortality rate (thirty-three cases) was 47 per cent. Undoubtedly the one factor that will further lower the death rate is the more universal use of prophylactic injections, this is a desideratum hard to achieve, however, because certain apparently very trivial wounds will prove later to be the source of the disease. All compound fractures, gunshot wounds, deep punctured wounds, "street" wounds and "farm" wounds should be treated prophylactically. Ordinary wounds acquired in the home, or in clean places, free from possible fecal contamination, or while bathing at the shore, should not require the injection. A dressing should never be applied to the "insertion" area of a smallpox vaccination.

The consideration of our cases, and a review of the opinions of many others, lead us to recommend early and large doses of tetanus antitoxin given by the intramuscular and intravenous routes, while we cannot recommend the further use of intraspinal injections. The use in tetanus of intravenous antitoxin by the "forced drainage" method, as employed by Kubie and by Fremont-Smith, Putnam and Cobb in poliomyelitis and multiple sclerosis, seems to us theoretically attractive but practically impossible.

SUMMARY AND CONCLUSIONS

1 Thirty-three additional cases of tetanus are reported from the Massachusetts General Hospital, making a total of 149 cases. Since 1896, when antitoxin was first used, the mortality has declined from 80 to less than 47 per cent.

2 Prophylactic injection of antitoxin (1,500 units) is indicated in cases of deep or puncture wounds that may be contaminated. In unusually suspicious cases

this should be repeated once or even twice at intervals of ten days.

3 The wound should, when possible, be debrided and kept open.

4 After the onset of tetanus, every effort should be made to conserve the patient's strength by the maintenance of nutrition and fluid balance, and by the combating of muscle spasms.

5 Tribrom-ethanol is a useful drug for the control of spasms.

6 As soon as the diagnosis is made, serum should be given intravenously, intramuscularly or both in daily doses of from 20 to 80 thousand units up to a total of 300 thousand units.

7 In hypersensitive subjects the process of desensitization must be instituted as soon as possible.

8 There are no theoretical or practical grounds for the recommendation of the intraspinal administration of antitoxin.

9 Serum reactions may be expected in about one third of all cases treated. The immediate reactions are commonest from two to five days after the initial dose of serum, and the delayed reactions from the tenth to the fifteenth day. No fatal reactions were encountered in the present series.

ABSTRACT OF CASES

CASE 1—Girl, aged 4. Smallpox vaccination. Onset of symptoms in twenty days, headache, pain in back of neck, convulsions. Died in convulsion with temperature 108. Total antitoxin, 40,500 units, intravenous 30,000, intramuscular 10,500.

CASE 2—Man, aged 55. Cut thumb on bottle. Onset of symptoms in sixteen days. Had lame jaw, for which he went to dentist and had convulsion on way to dentist's office. Later developed trismus, and spasm of neck and leg muscles. Total antitoxin 340,000 units, intravenous and intramuscular. Recovered.

CASE 3—Boy, aged 2 years and 10 months. Wound inside nose from foreign body. Onset of symptoms in probably six days. Died in convulsion. Total antitoxin 20,500 units.

CASE 4—Man, aged 54. Wound of thumb while working around barn. Symptoms began in twelve days, with trismus. Developed convulsions. Total antitoxin 180,000 units. Recovered.

CASE 5—Boy, aged 10. Blister on heel. Onset of symptoms doubtful, probably thirty days. Developed trismus, risus sardonicus, slight opisthotonos, frequent convulsions. Total antitoxin 126,500 units. Recovered.

CASE 6—Boy, aged 6. Smallpox vaccination. Onset of symptoms in twenty-six days. First diagnosis poliomyelitis, later, with development of trismus and other signs, diagnosis changed to tetanus. Total antitoxin 70,000 units. Recovered.

CASE 7—Boy, aged 9. Nail wound of foot. Developed symptoms in twelve days, trismus, lame back and shoulders, spasm of legs. Total antitoxin 180,000 units. Recovered.

CASE 8—Man, aged 71. Skin lesions on hands attributed to a Puerto Rican parasite. Incubation period not known. Developed trismus, and B tetani found in lesions. Total antitoxin 160,000 units. Recovered.

CASE 9—Man, aged 52. Wound of hand from chicken wire. Onset of symptoms in twenty-one days. Developed trismus, spasm of neck muscles, opisthotonos and convulsions. Died in respiratory failure with temperature 106.5. Total antitoxin 310,000 units.

CASE 10—Boy, aged 16. Lacerated wound of toe from horse stepping on it. Onset of symptoms in two and two-thirds months. Developed trismus, rigid neck and convulsions. Difficulty in breathing led to tracheotomy, which gave only temporary relief. Died in convulsions. Total antitoxin 240,000 units.

CASE 11—Girl, aged 7. Lacerated wound of face. Onset of symptoms in six days. Developed trismus, spasm of neck

muscles, opisthotonos and died in convulsions Total antitoxin 30,000 units

CASE 12—Man, aged 22 Shotgun wound causing compound fracture of femur Given prophylactic antitoxin, 1,500 units Local tetanus in twenty one days, trismus in twenty-four days Total antitoxin (following desensitization) 178,600 units Recovered

CASE 13—Boy, aged 14 No history of trauma Onset of symptoms with trismus, facial asymmetry, stiff back, and spasm of left leg and back. Total antitoxin 100,000 units Recovered

CASE 14—Girl, aged 3 Superficial scratches Onset of symptoms in forty-three days Developed trismus and painful spasms of back and abdomen Total antitoxin 40,000 units Recovered

CASE 15—Man, aged 31 Lacerated wound of thumb Onset of symptoms in five days Developed trismus, painful spasm of all muscles, and opisthotonos Total antitoxin 160,000 units Recovered

CASE 16—Woman, aged 63 Dirty laceration of leg Onset of symptoms in five days Developed trismus, stiff neck, and generalized convulsions Died in respiratory spasm Total antitoxin 200,000 units

CASE 17—Girl, aged 4 Superficial dirty wound of face Onset of symptoms in seventeen days Developed trismus, stiff neck, and frequent generalized convulsions Total antitoxin 200,000 units Recovered

CASE 18—Boy, aged 6 "Thorn in foot" wound became septic. Also, smallpox vaccination one month later Symptoms developed one month after vaccination (incubation period thus doubtful) Had trismus, general muscle spasm and opisthotonos Total antitoxin 110,000 units Recovered

CASE 19—Man, aged 36 Incision and drainage of septic hip joint Onset of symptoms in twelve days Chief sign was trismus Total antitoxin 210,000 units Recovered This case suggests the possible introduction of B tetani in catgut, at time of operation

CASE 20—Man, aged 67 Punctured wound of foot (nail) Onset of symptoms in sixteen days Developed trismus spasm of neck and leg muscles Total antitoxin 113,000 units Recovered.

CASE 21—Man, aged 45 Excision of sarcoma of leg (aseptic operation with dressing of silver-foil) Onset of symptoms in five days Developed trismus, spasm in neck, back and legs, extraordinary severe cramps in abdominal muscles Total antitoxin 145,000 units Recovered

CASE 22—Man, aged 36 Nail wound of foot Onset of symptoms in ten days Developed trismus, spasm of neck and back muscles, convulsions and opisthotonos Total antitoxin 40,000 units Died in convulsions shortly after admission.

CASE 23—Man, aged 57 Nail wound of foot Onset of symptoms in twelve days Developed trismus, stiff neck, general muscular rigidity, and convulsions Total antitoxin 61,500 units Died in convulsions shortly after admission

CASE 24—Boy, aged 7 Leg crushed by automobile. Onset of symptoms in seven days Developed trismus, general muscular rigidity, opisthotonos and convulsions Total antitoxin 30,000 units Died five hours after admission.

CASE 25—Boy, aged 13 Bullet wound (.22 caliber) of back. Onset of symptoms in nine days Developed trismus, generalized muscular stiffness and convulsions Total antitoxin 30,000 units Died five hours after admission in acute spasm of respiratory muscles

CASE 26—Man, aged 56 Compound fracture of leg street accident Wound became septic Onset of symptoms in fourteen days Developed trismus generalized muscular stiffness and convulsions Total antitoxin 155,000 units Died in convulsions

CASE 27—Boy aged 10 Fourth of July accident to finger, with cap-pistol. Onset of symptoms in fifteen days Symptoms were mild and subsided, on eighteenth day after injury went into opisthotonic spasm at home. Not brought to hospital till twenty-third day after injury, when he had trismus and convulsions Striking improvement on day after institution of treatment. Total antitoxin 110,000 units Recovered

CASE 28—Boy, aged 16 Compound fracture of ankle in street, treated at home Onset of symptoms in six days Developed trismus, spasm of neck and back muscles, convulsions, opisthotonos Total antitoxin 170,000 units Died in convulsions

CASE 29—Man, aged 56 Lacerated wound of elbow Onset of symptoms in nine days Developed trismus, stiffness of neck and back muscles, opisthotonos Total antitoxin 300,000 units Recovered

CASE 30—Girl, aged 6 Smallpox vaccination Onset of symptoms in thirteen days Developed trismus, generalized convulsions and opisthotonos Total antitoxin 30,000 units Died in convulsions few hours after admission

CASE 31—Boy, aged 16 Simple fracture of ankle, followed by open reduction in hospital Patient worked in stable. Onset of symptoms in eighteen days Developed trismus, generalized convulsions and opisthotonos Total antitoxin 81,500 units Recovered

CASE 32—Man, aged 32 Lacerated wound of wrist while working in orchard. Onset of symptoms in six days Developed trismus, generalized convulsions, and opisthotonos Total antitoxin 185,000 units Died

CASE 33—Woman, aged 51 Kidney operation (nephrectomy) Onset of symptoms in nine days Developed trismus and convulsions Total antitoxin 80,000 units Died in convulsions

264 Beacon Street

ABSTRACT OF DISCUSSION

DR FREDERIC W TAYLOR, Indianapolis As has been suggested, the local lesion must receive prime consideration. It after all, initiates the entire tetanic syndrome. That this point has been frequently overlooked is borne out by a study of any series of tetanus cases. In a small series that I had occasion to review, seventeen patients were admitted to the hospital with healed skin lesions. These wounds were not touched, were not excised, were not explored, for fear of disseminating tetanus toxin in the body. The toll of this overcautious procedure was twelve lives, a mortality in excess of 70 per cent. In the last three years I have seen five autopsies on patients dying with tetanus. In three of these cases, foreign bodies were removed from the local wound at the autopsy table. These were bathed in pus containing *Clostridium tetani* and surrounded by the usual gray necrotic tissue. In order to prevent or minimize the danger of such accidents, I believe that all tetanus cases should be admitted to the hospital only by way of the operating room. Here the local wound should be excised if possible, if not, it should be thoroughly explored and a débridement done. I am glad to hear the authors voice their protest against intrathecal administration of antitoxic serum. I am quite in accord with this view and feel not only that it is an inefficient and ineffective route by which to administer this serum but that it does harm in giving the clinician a false sense of security as to just what that serum will do. I should like to take issue with the authors on the dosage of tetanus antitoxin. Given prophylactically, the serum is a specific without a peer in the biologicals. Used in the treatment of tetanus after the disease has once developed, it certainly is not a specific and should be considered as an adjunct to any other treatment. I believe that 50,000 units or at most 100,000 units is quite amply sufficient to neutralize toxin in the tissues and blood stream. I believe moreover that huge doses of tetanus antitoxin have done harm, not because they are useless, not because they cause serum sickness and not because of immediate anaphylactic reactions. Large doses of antitoxin have done harm in giving a false sense of security to the clinician. He therefore neglects the local lesions, passes over lightly deep relaxation of his patient, and pins his hope on the specific.

DR RICHARD H MILLER, Boston I am glad that Dr Taylor emphasized the local wound, because that is of great importance. We did not say very much about it. I know that some cases of tetanus are so mild the patient will get well anyway. Some cases are so virulent that nothing can be done for them, but there is a small group in between in which careful and effective treatment will save life.

RECTAL GONORRHEA IN WOMEN

CLEMENT L. MARTIN, MD

CHICAGO

Gonococcic infection of the rectum decidedly is not an uncommon complication in women who harbor this infection in the cervix or the urethra. Symptoms often are absent, nearly always they are mild. As a consequence the disorder rarely is diagnosed. Years ago Jullien¹ stated that rectal gonorrhea "is a disease one sees only if one looks for it." This statement is still pertinent. The lesion commonly results from genital gonorrhea. Although not uncommon, it is not very frequently encountered in the ordinary run of examinations in women in a proctologic practice. The disease is rather uncommon in males and rare as a primary ailment in women. Of 220 men having gonorrhea in the Chicago House of Correction Hospital, a group in which the incidence would be expected to be relatively high, De Bere² found rectal gonorrhea in a little over 2 per cent of the cases.
